In addition, calibration assessment should also consider the spatial scale of the input data to the ILRG Model. For example, while the model separately simulates the irrigation operations in the EBID subareas of Rincon, Leasburg, Eastside Mesilla, and Westside Mesilla, it is appropriate to evaluate the model performance for certain aspects of EBID using District totals. This is because portions of the EBID data used in the modeling are reported only as EBID totals. Care must be given in judging model results at a spatial scale that is finer than the spatial scale of the input data. A summary of the spatial scale of selected input data for the ILRG Model is shown in **Table 23-1** and discussed in Section 23.0.

Coors Opinion 28 *- A second important indicator of a well calibrated model is low operational bias. The cumulative residual between the modeled values and observed values is an indicator of model bias and should not exhibit noticeable patterns or trends in a well calibrated model. If the model is replicating history (Project operations in this case) objectively the absolute residual should appear random and cumulative residual should display no distinct multiannual trends indicated by significant departures from the zero line. Analysis of the bias in the same 26 locations exhibits the opposite, and the flaw is evident when viewing the residual and cumulative residual trends of the Rio Grande at El Paso, Figure 2. (page 15).*

Response:

The cumulative residual described by Mr. Coors is not the same as operational bias. Operational bias, also known as mean error, is defined as the difference between the computed mean of a simulated output and the computed mean of the observed data over all or a portion of the simulation period. The cumulative residual shows how differences between modeled and observed values accumulate through time during the simulation period. Virtually all models of complex systems will show cumulative residuals of model outputs trending in positive and negative directions over short time periods such as are shown for the Rio Grande at El Paso in Figure 2 of the Coors Supplemental Report. The suggestion by Mr. Coors that the cumulative residual represented by the heavy blue line should hover very closely around zero is an ideal that is rarely achieved in hydrologic modeling of complex systems.

In addition, Figure 2 in the Coors Supplemental Report does not provide context for the amount of the residuals and cumulative residuals. The middle right graph in **Figure 28-2** shows the cumulative residual for the Rio Grande at El Paso gage as a percentage of the cumulative El Paso flow over the 1940 – 2017 study period. This puts the cumulative residual error at the El Paso gage in proper perspective. The maximum cumulative residual ranges from -1.8% to +0.6% which is excellent.

Coors Opinion 29 *- The New Mexico experts fail to create accurate representations of no pumping conditions in their hypothetical scenarios. The hypothetical runs (Runs 2, 3, 4, 5, and 6) simulate scenarios in which groundwater pumping is turned off for regional and basin-wide combinations of water users. New Mexico experts modeled the hypothetical scenarios by simply setting groundwater pumping to zero in the no-pumping areas. Modeling the no-pumping condition in this way fails to adequately represent changes that would occur in on-farm processes resulting from the unavailability of groundwater supply. While the irrigated acreage on the primary groundwater users is properly reduced to zero, the irrigated acreage of supplemental groundwater users is not reduced in response to decreased water supply. The irrigated acreage would decrease or a crop requiring less water would be produced to respond to the decrease in available water, as shown in Eq (6). ILRG modelers selected RiverWare methods on the RiverWare "Water User" objects requiring irrigated acreage and the evapotranspiration (ET) rate be entered as inputs. Historical irrigated acreages and ET rates are also used in all the hypotheticals. Not allowing irrigated acreages or ET rates to change (reduce) for scenarios in which water supply significantly decreases results in unrealistic results because the modeling of monthly on-farm processes through the irrigation season are unreasonable. (page 16).*

Response:

In my experience, it is common in modeling alternative scenarios of historical irrigation to leave the irrigated acreage and cropping pattern at the historical values in simulations of alternative scenarios, including no pumping or reduced pumping scenarios. This is how reduced pumping scenarios were simulated using the H-I Model of the Arkansas River for the Kansas v. Colorado litigation. This procedure is also similar to how engineers in Colorado analyze historical use for changes in irrigation water rights in the Colorado water courts. In these analyses, the irrigated area is typically simulated at the maximum irrigable acres evident in aerial photographs. In each year of the historical simulation, the upper limit of the crop consumptive use is based on the crop-weighted CIR multiplied by the simulated irrigated area. During water short years, the actual crop consumptive use is limited to the historical farm headgate deliveries multiplied by the maximum on-farm irrigation efficiency.

In the no pumping or reduced pumping runs of the ILRG Model, the simulated irrigation supply delivered to the farms will often be less than the irrigation water demand for the historical irrigated area and cropping pattern resulting in irrigation water shortages. In these water short conditions, the simulated irrigation consumptive use is limited to the available supply times the maximum on-farm irrigation efficiency.

While it is true that in the real-world farmers without access to wells may reduce the irrigated area and change their crops to conform to the expected limited surface water supply, it is reasonable to assume that the limited supply would be consumed at the same maximum irrigation efficiency resulting in the same consumptive use of applied surface water. In other words, even if the acres and assumed crops were changed in the alternative runs, the consumptive use would still be the result of the available supply times maximum on-farm irrigation efficiency.

If the simulated consumptive use is the same whether or not the simulated acreage is reduced and the crops are changed, then there is little to be gained by speculating how the farmers would respond to the reduced irrigation supply in terms of the modeling results. Note also that Dr. Hutchison did not reduce the irrigated area is his simulation of reduced pumping scenarios.

Coors Opinion 30 *- This is a standard method to develop reservoir local inflows. However, because estimated evaporation and measurement error are part of the calculated mass balance equation, and bank storage and reservoir seepage are elements in the actual water balance of the reservoir and is not included in the calculated water balance, there are numerous months for which a negative value is calculated for this quantity. This is a common result from a mass-balance approach to developing reservoir inflows. It causes problems for modeling the hypothetical scenarios as the inflow to Caballo Reservoir would be different in the different hypothetical scenarios that have a significant difference in Caballo storage throughout the run, as bank storage and seepage are dependent on reservoir storage levels. The NM experts did not consider that there would be difference in bank storage effects in alternative runs. (page 18).*

Response:

Caballo Reservoir is an operational reservoir that helps to regulate releases for power production from Elephant Butte Reservoir for subsequent downstream delivery to meet Project water demands. It is not expected that the function of Caballo Reservoir as a regulating reservoir would be materially different in alternative scenarios compared to the historical operation over the long term, and therefore any differences in bank storage effects would be positive and negative and largely cancel each other out.

Coors Opinion 31 *- There is a second, more significant problem with this quantity. The RiverWare model introduces erroneous (non-historical) water to the system here by means of an inappropriate "method" being employed on this object. When during the course of a model run, the simulated releases from Elephant Butte are not large enough to compensate for the negative inflows input to the system at the "RGabvCaballo" reach, a negative outflow would result from the reach. This is problematic for the model and must be addressed. Hydros' solution to the problem was to select the "Negative Outflow Unidentified Loss" method which adds any additional flow to the reach necessary to make the outflow zero. This added water is not part of the historical inflow development process and represents water erroneously added to the system at Caballo. (page 18).*

Response:

This issue was described by Mr. Coors in his first deposition in February 2020. The New Mexico experts reviewed this matter and added a rule to the RiverWare simulation of Elephant Butte Reservoir that computes a minimum monthly release equal to the computed unmeasured negative inflow (loss) between Elephant Butte Reservoir and Caballo Reservoir. This additional rule corrected the mass balance issue that was identified by Mr. Coors.

Coors Opinion 32 *- Creating management rules and tuning a set of simplistic operational parameters to accurately simulate the complexity of real historic operations of the Project at a monthly scale is an overly ambitious goal. Physical processes are governed by physical laws that behave consistently. Given the same set of initial conditions, the dynamics of water in a physical system governed by physical laws will always be the same. The same is not true of management processes; management processes like Rio Grande Project operations are governed by legal structures, historical practice, and subjective decision making. Given the same set of initial conditions the dynamics of water governed by management process can vary significantly for a variety of reasons including the political climate, current system operator, one-off conditions, and any number of other factors. This fact makes characterizing historical Project operations with a sufficient degree of accuracy to support impacts analysis using hypotheticals an impossibility. (page 21).*

Response:

I disagree that the dynamics of the Rio Grande Project management processes cannot be modeled with sufficient accuracy. The historical procedures for allocating water and operating the Project reservoirs to release sufficient water to meet water orders are generally well established, understood, and amenable to modeling. The excellent calibration statistics for Caballo Outflows summarized in **Table 28-1** and the graphical comparison of simulated and observed releases shown in **Figure 28-1** are evidence of the efficacy of the RiverWare rules in simulating Project operations.

Coors Opinion 33 - *These unanticipated deviations make "tuning" the model to simulate management processes a highly uncertain exercise with only modest success even possible. When the quantification of pumping impacts is dependent on the model replicating historical conditions precisely, tuning a few simple model parameters to attempt to closes match the intricacies of real-world management processes to a degree suitable for closely matching historical operations is unattainable. (page 21).*

Response:

While there were occasional ad hoc historical deviations from standard Project operating practices, the RiverWare simulation rules produce a well-calibrated model as evidenced by the calibration statistics and graphical comparisons of predicted and observed flows presented in Section 28.0.

The statement that quantification of pumping impacts depends on precise model replication of historical conditions by Mr. Coors is not realistic and sets an impossible standard. A model need not be perfect to be useful and reliable. As discussed in the response to Coors Opinion 34, differences in model outputs from simulated scenarios (e.g., a no pumping run vs. the Historical Base Run) can be more accurate than the model predictions of the individual scenarios because of the cancelling of similar errors that are present in both scenarios.

In order for the differences between scenarios simulated in this case to be reasonable and accurate, the simulation model needs to (a) simulate the entire area from Elephant Butte Reservoir to Fort Quitman, (b) use monthly stress periods that facilitate analysis of the relatively rapid temporal response and interaction between the surface water features and the shallow alluvial aquifers, (c) simulate Project and irrigation system operations using rules that facilitate dynamic response to changing conditions in alternative scenarios, and (d) be calibrated to show a reasonable match between modeled and observed historical flows on a seasonal or annual basis. The updated ILRG Model succeeds in all of these areas.

The relatively simple tuning of the operational rules that produces a good model calibration without overparameterizing the model as demonstrated in tables and charts in Section 28.0.

Coors Opinion 34 *- [Deposition testimony of Michel Estrada-Lopez] characterizes precisely what is described above as a management process. This process is a fundamental aspect of Project operations that are purportedly "well represented" by rules and operational tuning factors. Her description of how the process of determining the annual allocation for the Project actually takes place certainly highlights the subjective and evolutionary nature of this operation. These characteristics make capturing historical Project operations with rules and simple tuning parameters essentially impossible. The failing calibration analysis and operational bias analysis presented above demonstrate what would be expected from a model that attempts to capture with static logic a real-world historical operational process like annual Project allocation as described by Ms. Estrada-Lopez. (page 22).*

Response:

The deposition testimony of Ms. Estrada-Lopez cited by Mr. Coors details the annual process involved in Project accounting. For modeling purposes, it is not necessary to simulate every detail of the Project accounting in order for the model to be reliable in analyzing the claims and counterclaims in this case. Application of the ILRG Model in this case will typically involve computing differences between model runs (e.g., a no pumping run minus the Historical Base Run). When computing these differences, model error resulting from insignificant fine accounting details that are not incorporated in the simulation rules will tend to be present in both of the model runs, and therefore this error will tend to cancel out when the runs are differenced. A consistent set of simulation rules is applied in the ILRG Model simulations of the Historical Base Run and alternative scenarios and this allows the changes in input data or assumptions for different runs to be reflected in the computed differences in model outputs.

This is analogous to ground water models that do not and cannot represent all of the real-world spatial heterogeneity of the simulated ground water system. Instead, ground water modelers represent the aquifer hydrogeology using hydraulic conductivity and storage coefficients that are spatially smoothed and approximate representations of real-world variability. When the ground water models are calibrated to reasonably replicate historical conditions, they are judged ready for use in simulating alternative scenarios.

Ms. Estrada-Lopez's testimony also describes the process for reviewing and potentially updating the Operating Agreement Manual and/or the accounting spreadsheet. The ILRG Model reasonably simulates the processes set forth in the Operations Manual and in the Accounting Spreadsheet. To the extent that the manual or spreadsheet are revised to a substantive degree, relevant ILRG Model rules can be modified accordingly to simulate those changes beginning in the year they are implemented. Historically, most of the accounting refinements that have been implemented are in the category of fine accounting details that need not be represented in the ILRG Model rules. As described above, to the extent the absence of these details contributes to model error, this error will tend to cancel out when differencing model runs.

Coors Opinion 35 *- It is my opinion that based on the calibration results for Run 1 the idealized monthly Project operations in the RiverWare model do not represent historical monthly Project operations to an acceptable degree to model non-historical hypothetical scenarios and how Project operations would change under hypothetical, non-historical conditions on a monthly basis. (page 22).*

Response:

As shown in the tables and figures in Section 28.0, the ILRG Model is well calibrated on a seasonal and annual basis and also generally matches the patterns of the monthly flows during the irrigation season and non-irrigation season. Because the robust performance of the ILRG Model is achieved with rules that facilitate dynamic response to changing conditions, it is my opinion that ILRG Model produces reasonable and reliable results in simulating alternative scenarios.

Coors Opinion 36 *- When results from the New Mexico experts' model runs are temporally aggregated to annual averages and spatially aggregated into large project areas (Rincon, Leasburg, and Mesilla), the uncertainty in the results is reduced. The simplest way to limit uncertainty in data, especially in the case of modeling the LRG system would be to aggregate. When data is aggregated spatially and/or temporally, the uncertainty in its values decreases. (page 22).*

Response:

There is agreement that aggregating results temporally and spatially reduces uncertainty in the ILRG Model results. Such aggregation is reasonable and appropriate in assessing the model calibration, interpreting the model results, and in using the model to evaluate the claims and counterclaims in this case.

Coors Opinion 37 *- Table 5 shows the same set of calibration results as were presented in Section 6.1.1, but model results are aggregated to an annual timestep. When comparing Table 5 to Table 2 (Section 6.1.2, above) it is apparent that the performance improves. Further improvement would be expected by spatially aggregating within the ILRG model as well. The results still show significant problems with the calibration of the model even at the annual level, and thus specific quantitative annual results from the ILRG model are informative, but still not reliable. (page 23).*

Response:

As discussed extensively above, it is reasonable and appropriate to aggregate and assess the ILRG Model results primarily using irrigation season totals. There is also some utility in assessing the model performance in simulating the Rio Grande flows at the El Paso and Fort Quitman gages on the basis of annual totals from an overall mass balance perspective because the simulated flows at these gages integrate all upstream operations.

The annual results presented in Table 5 of the Coors Supplemental Report and all other annual totals presented in the report and in backup spreadsheets are plagued with an arithmetic error. All of the annual totals were computed by Excel formulas based on the sum of the monthly values from one December through the next December. In other words, all annual totals reflect the sum of 13 monthly values. For example, the annual flow for 2010 was computed as the sum of the monthly flows from December 2009 through December 2010.

Coors Opinion 38 *- Considering Run 2 as the baseline or 1938 Compact condition and Run 1 as the historical deviation from the 1938 Compact condition, comparing results from the two runs at an appropriate spatial and temporal scale shows the impacts of groundwater pumping throughout the basin as all other processes that might affect the dynamics of water in the system are the same. Comparing results from these two scenarios isolates the impacts of groundwater pumping on surface water conditions, groundwater conditions, and Project operations. The results clearly substantiate Texas's primary claim. (page 24).*

Response:

It is illogical and inappropriate to use the results from Run 2 of the ILRG Model when all pumping is turned off (New Mexico, Texas, and Mexico) to attempt to substantiate the Texas claim that New Mexico pumping has reduced the supply to Texas. Run 2 does not isolate the effects of New Mexico's pumping on deliveries to Texas. The impacts of pumping by Texas in the Mesilla basin and the Hueco basin contribute to computed differences in the ILRG Model results for Run 2 and Run 1.

Coors Opinion 39 *- Dry periods such as the mid-1950's when pumping in New Mexico was prevalent are evident by the depleted groundwater condition. It is evident too that the duration of depleted groundwater conditions is multiple years, and that the groundwater condition remains somewhat depleted for the remainder of the run after 1950. This is consistent with the Texas claims and illustrates why Texas chose to develop a model with an annual stress period. (page 26).*

Response:

The fact that the ILRG Model simulates multi-year impacts to ground water elevations during dry periods does not mean that a model with annual stress periods is appropriate for use in analyzing the Texas complaint. While impacts to ground water storage are of interest in this case, the impacts to Project surface water supplies are the primary focus. As has been clearly demonstrated through analyses of historical data and through the simulations using the ILRG Model, impacts of pumping, changes in irrigation practices, and changes in Project operations affect surface water deliveries on a monthly or seasonal basis. The typical rapid response of drains to pumping and irrigation recharge is illustrated in **Figure 23-1** and **Figure 23-2** that are discussed in the response to Coors Opinion 8.

Coors Opinion 40 *- Clearly, the seepage out of the Rio Grande in these service areas in New Mexico is significantly greater in the historic scenario, Run 1, than in the no pumping baseline scenario, Run 2. (page 28).*

Response:

It is not appropriate to evaluate the effects on river seepage caused by New Mexico pumping using Run 2 (All Pumping Off). See the response to Coors Opinion 38.

Coors Opinion 41 *- Finally, New Mexico's RiverWare model simulates an idealized version of the determination of the annual allocation for EPCWID for each year of the run. Results show that the EPCWID allocation is negatively impacted by the historical pumping represented in Run 1 compared to the no pumping condition of Run 2. (page 28).*

Response:

It is not appropriate to evaluate the effects on Texas allocations caused by New Mexico pumping using Run 2 (All Pumping Off). See the response to Coors Opinion 38. As discussed in Section 30, New Mexico pumping impacts irrigation season deliveries to EPCWID by an average of 17,800 AF during 2006-2017. This is much less than the impact of the 2008 OA on New Mexico computed in Run 11 that averaged 54,600 AF during the same period.

Coors Opinion 42 *- A comparison of the flows in the river at El Paso between Run 2 and Run 1 of New Mexico's ILRG model clearly indicates that pumping in New Mexico has negatively impacted flows at El Paso. (page 29).*

Response:

It is not appropriate to evaluate the effects on Rio Grande at El Paso flows caused by New Mexico pumping using Run 2 (All Pumping Off). See the response to Coors Opinion 38. In any event, the El Paso gage is not a Compact delivery point and changes in El Paso flows caused by New Mexico pumping are not an appropriate measure of impacts to Texas.

Coors Opinion 43 *- Comparing Run 1 and Run 2 and their results for El Paso flows provides an answer from New Mexico's own model to Spronk and Hydros' repeated contentions that the Texas analysis in general, and Brandes's analysis in particular, is "overly-simplistic" and that the depleted El Paso flows issue is actually much more complex with many possible explanations. Run 1 and Run 2 are formulated to isolate the effects of pumping with <u>all else equal</u>. The Run 2 scenario as conceived by New Mexico experts is very similar in concept to a 1938 Compact condition of the basin. It simulates a condition in which there is no pumping throughout the LRG basin, as was the case during the 1930-1950 period. It is striking how similar the 1930-1950 double mass analysis data and extended trend line from Brandes' report are to the same double mass curve generated from the ILRG model Run 2 results. (page 30).*

Response:

Mr. Coors is incorrect in stating that there was no pumping in the LRG Basin during the 1930-1950 period. Large scale development of supplemental irrigation wells commenced in the late 1940s, and non-irrigation Irrigation pumping for M&I and other uses started earlier, most notably in the El Paso and Juarez areas.

The general long-term agreement between change in El Paso flow shown in the Brandes double-mass curve (as revised by Coors) and the ILRG Model (Run 2 vs. Run 1) is a validation of the efficacy of the ILRG Model.

Figure 15 in the Coors Supplemental Report compares cumulative <u>annual</u> El Paso flows from the revised Brandes double-mass curve analysis against the ILRG Model results. These comparisons of annual flows do not distinguish changes in flows during the irrigation season from changes in flows during the non-irrigation season. As described above, it is the changes in irrigation season flows that are most important in this case, with changes in irrigation season deliveries to the end users being the relevant measure of impacts, not changes in flow at the El Paso gage.

When all of the pumping in the Rincon and Mesilla Valleys is turned off in the Texas Model, far too much water shows up at El Paso, more than shown by the Brandes double-mass curve analysis because of the lack of re-operation in the Texas Model. This is clear evidence of the failure of the Texas Model to produce reasonable and believable results.

Coors Opinion 44 *- The New Mexico models corroborate that the observed decrease in flows at El Paso from the time when groundwater pumping began in New Mexico appears to be rightly attributed to this pumping. (page 32).*

Response:

The results from Run 2 cannot be used to attribute the effects of New Mexico pumping because all pumping is turned off in Run 2, including pumping by Texas and Mexico in the Mesilla and Hueco basins. See the response to Coors Opinion 38.

Coors Opinion 45 *- Modeling monthly Project reservoir operations is not necessary to demonstrate the impact of New Mexico groundwater pumping on deliveries to Texas water users, as has been substantiated throughout this report and is demonstrated convincingly in Dr. Hutchinson's report describing the Texas model. However, referencing these results from the New Mexico experts' runs of their own model further refines the narrative of how New Mexico's pumping impacts on Texas water users. (page 32).*

Response:

As discussed extensively in the SWE Report, the Texas Model is unreliable because it includes no capability for dynamic simulation of Project operations. In order to approximately match the historical change in El Paso flow evident in the Brandes double-mass curve analysis, Dr. Hutchison turns off only 60% of the pumping by New Mexico and Texas in the Rincon and Mesilla basins. Because of the lack of reoperation in the Texas Model, turning off all of the pumping in the Rincon and Mesilla basins causes too much water to flow out the bottom of the Texas Model at El Paso.

Notwithstanding the lack of reoperation, the Texas Model runs performed by Dr. Hutchison are not appropriate for attribution of impacts caused by New Mexico pumping because these runs also reflect the effects of pumping by Texas wells in the Mesilla basin.

Coors Opinion 46 *- Table 7 shows that during this 1950-1956 drought period, as a result of groundwater pumping, the impact to groundwater elevations grows, the impact to seepage increases and the allocation to EPCWID is negatively impacted as well. These values are bordered in orange in Table 7. (page 33).*

Response:

The results from Run 2 cannot be used to attribute effect of New Mexico pumping because all pumping is turned off in Run 2, including pumping by Texas and Mexico in the Mesilla and Hueco basins. See the response to Coors Opinion 38.

Coors Opinion 47 *- What is important about this first sequence of years is that it shows that the negative impacts of groundwater pumping continue to accrue even when the basin is no longer in drought and allocations return to full. (page 34).*

Response:

Impacts to ground water storage can reasonably persist even when full supply conditions return. That the ILRG Model simulates this phenomenon shows that the ILRG Model is robust and can simulate both short-term and long-term impacts from pumping. Mr. Coors has not shown how impacts to ground water storage in New Mexico are injurious to Texas.

Coors Opinion 48 *- While there is no realized impact to the allocation during these years, there is a growing deficit in stored water in the reservoirs. This storage differential can be characterized as a growing potential impact to Texas. (page 34).*

Response:

The results from Run 2 cannot be used to attribute effects of New Mexico pumping because all pumping is turned off in Run 2, including pumping by Texas and Mexico in the Mesilla and Hueco basins. See the response to Coors Opinion 38.

Potential impacts are not the same as actual impacts. Depletions to reservoir storage do not translate into impacts on Project deliveries until the storage account(s) empty. Impacts from pumping can accumulate in storage during full allocation years during which time portions of the accumulated impacts are lost to evaporation and seepage. Reservoir spills will also cancel out accumulated storage impacts.

Coors Opinion 49 *- When New Mexico pumps groundwater, it effectively and inappropriately borrows Project water from the future. Some of this borrowed water ends up impacting New Mexico by the same mechanism described above. But because New Mexico water users receive the benefit of the water when it is pumped from the ground, the impact does not represent an injury. They effectively borrowed from their own future water. There is an injury to Texas water users, however, because a significant portion of the Project water New Mexico borrowed through pumping belongs to the Texas as defined* *in the 1938 Rio Grande Compact. This is the essence of the complaint and the source of the injury to Texas water users. (page 35).*

Response:

The results from Run 2 cannot be used to attribute effects of New Mexico pumping because all pumping is turned off in Run 2, including pumping by Texas and Mexico in the Mesilla and Hueco basins. See the response to Coors Opinion 38.

Mr. Coors' assertions about future impacts caused by New Mexico pumping also apply to Texas pumping. The extent to which New Mexico or Texas pumping impacts Project water deliveries in the future depends on whether such pumping causes depletions of surface water flow that when translated through lens of Project operations results in material reductions in deliveries of Project water to the end users in Texas and/or New Mexico. The only way to evaluate such impacts is using the ILRG Model with its capability for dynamic reoperation response to changes to ground water and surface water flows caused by pumping. The Texas Model is incapable of such analysis.

Coors Opinion 50 *- Rather ILRG model results indicate that pumping in the Hueco has no significant impact on releases from Caballo Reservoir or Rio Grande flows at El Paso. (page 35).*

Response:

As described in the response to Ferguson Opinion 3. Hueco pumping does impact upstream Project operations, including Caballo Reservoir releases and El Paso flows. However, in many years some, but not all, of these impacts are offset by EPW WWTP discharges.

Coors Opinion 51 *- The appropriate conclusion from this simple comparison (Run 6 vs. Run 2) is that pumping in the Hueco Bolson basin has essentially no impact on Project operations or flows in the river at El Paso. Pumping in the Hueco Bolson resulted in differences in the releases from Caballo and the flows at El Paso by less than 1% on an absolute basis, and the changes were essentially unbiased, meaning that they were equally often increased as decreased. (page 37).*

Response:

Differencing the results between Run 2 (All Pumping Off) and Run 6 (Rincon-Mesilla Pumping Off) to compute the effects of pumping in the Hueco basin assumes that the ILRG Model is linear, which it is not. A more appropriate way to evaluate the effects of Hueco pumping is to make a run of the ILRG Model with the Hueco pumping turned off and compare the results to Run 1 (All Pumping On). This run and several variants are described in Section 31.0 (Runs 14, 14a, 14b, 14c, and 14d) and also in the response to Ferguson Opinion 3.

Coors Opinion 52 *- In order to make a comparison with Run 1 that isolates Hueco Bolson pumping, Texas legal counsel directed Precision to develop and conduct a run of the ILRG model that was not included in the set of runs disclosed by the New Mexico experts. Precision designed a scenario in which all groundwater pumping in the Hueco Bolson groundwater basin is turned off. This run of the ILRG model is titled "Run A". Comparing Run A back to New Mexico Run 1 provides an estimate of the impact of turning historical Hueco Bolson pumping off while maintaining historical pumping in the Rincon and Mesilla basins. (page 37).*

Response:

While Mr. Coors said that he turned off all ground water pumping in the Hueco in his "Run A" of the ILRG Model, review of the input and output files that he disclosed for this run shows this was not the case. The following are among the errors that were discovered in the configuration of Run A:

- Supplemental irrigation pumping and M&I pumping in Mexico were left on,
- M&I pumping in Texas by entities other than EPW was left on,
- All WWTP discharges (Haskell, Bustamante, Socorro, Juarez, and Fabens) were left on, and
- All urban deep percolation was left on.

Because of these errors, the results from the Run A made by Mr. Coors are not usable.

Coors Opinion 53 *- My conclusion from this comparison, much the same as the first one, is that according to the ILRG model, pumping in the Hueco Bolson basin has virtually no impact on Project operations or flows in the river at El Paso. (page 39).*

Response:

Because of the errors with how Run A was configured, the results from this run are not a reliable indication of the effects of Hueco pumping.

24.0 RESPONSE TO MORAN SUPPLEMENTAL REPORT

Ms. Jean Moran of Stetson Engineers, Inc. prepared a September 17, 2019 supplemental expert report on behalf of the United States ("Moran Supplemental Report") that described further review and analysis using the Texas Model and included two new model runs.

SWE was asked by legal counsel for New Mexico to review the Moran Supplemental Report and to prepare expert opinions to respond the opinions of Ms. Moran. A lack of response regarding a particular issue should not be interpreted as tacit agreement with the Moran opinions on that issue.

All of the criticisms of the Texas Model structure and inputs that are described in the SWE Report and elsewhere in the SWE Rebuttal Report also apply to the Texas Model runs described in the Moran Supplemental Report. The responses described below do not restate these criticisms but rather focus on particulars of the Texas Model runs performed by Ms. Moran.

Moran Opinion 1 *- To assess the impacts of pumping on surface water supplies, the Historical model run3 was modified to account for no pumping in an iterative process. First the MODFLOW WEL package was adjusted to eliminate irrigation, urban, and domestic pumping; in addition, deep infiltration attributed in the Texas Model to groundwater used for irrigation and urban supply was also eliminated. The Texas Model was rerun using these no pumping conditions. The No Pumping model run was compared to the Historical model run to evaluate and quantify changes (increases) in annual streamflow in the Rio Grande at El Paso Narrows that would have been available in the absence of groundwater pumping in New Mexico. These new No Pumping model run results with the final Texas Model update and confirm the model results described in our May 31, 2019 report.*

Response:

The first step in Moran's no-pumping run of the Texas Model was to turn off the irrigation pumping, non-irrigation pumping (urban and domestic), deep percolation from irrigation pumping, and deep percolation from urban pumping. Critically absent from this list of changes was turning off the WWTP discharges from the urban pumping. Without turning off these WWTP discharges, the Moran run does not simulate the offset from WWTP discharges when the results from this run are compared to the historical run. This error inflates the simulated impacts from pumping.

In the Moran no pumping run, all pumping in the Texas Model was turned off, including irrigation and non-irrigation pumping in the Texas portion of the Mesilla Valley. Therefore, the computed differences between the historical run and the no-pumping run reflect impacts caused by New Mexico pumping and Texas pumping.

Moran Opinion 2 *- The analysis for this supplemental report attempts to reasonably distribute the additional surface water made available by eliminating pumping in order to evaluate the sensitivity of the Texas Model to show the effect of no pumping on the surface water supplies for the Project. To make this analysis, adjustments were made to the MODFLOW Stream Flow Routing (SFR) package to distribute the increases in Rio Grande streamflow at El Paso Narrows calculated in the No Pumping model run to upstream diversions and farm deliveries based on historical distribution. The Texas Model was iteratively rerun to account for Project water deliveries and Rio Grande streamflow at El Paso Narrows gage.*

Response:

As has been discussed at length by the New Mexico experts, one of the fundamental flaws of the Texas Model is the absence of mechanisms for simulating the water allocation and delivery processes of the Rio Grande Project. The absence of such mechanisms causes the results from Texas Model runs that were presented in the Hutchison Report to be generally of little use because there is no simulated response of the Project operation to the changes simulated in alternative scenarios (e.g., reduced pumping scenarios). In the alternative scenario runs of the Texas Model runs that were presented by Dr. Hutchison, the reservoir releases and diversions are fixed at historical levels in all runs. Therefore, simulated changes in surface flows simply flow downstream and out of the model domain at the Rio Grande at El Paso gage.

Ms. Moran has attempted to remedy the severe shortcomings of the Texas Model by developing a crude iterative redistribution procedure that redistributes a portion of simulated changes in flow at El Paso to upstream diversions. This is tacit acknowledgement of the shortcomings caused by the lack of reoperation in the Texas Model.

While the redistribution mechanism implemented by Ms. Moran represents some improvement to the Texas Model, it has substantial shortcomings that create unrealistic results, especially in comparison to the more realistic reoperation capability that is inherent in the ILRG Model. The Moran process redistributes on average 84% of the simulated additional annual flow at El Paso to upstream river diversions at the Arrey, Leasburg, Eastside, and Westside Canals in proportion to relative historical annual diversions. The additional flow allocated to each canal is then distributed to terminal diversions (FHG deliveries) within each canal in proportion to the simulated values in the calibration run. This simple proportional redistribution of the additional El Paso flow to the upstream canals assumes a linear redistribution of the additional flow to the upstream canals in a highly nonlinear system. The simplified redistribution process used by Ms. Moran does not consider the following factors that would affect the distribution of additional river flow in no pumping or reduced pumping scenarios.

- Monthly and seasonal distribution of the additional annual El Paso flow,
- Changes in releases from Caballo Reservoir,
- Limits on canal capacity,
- Whether EBID or EPCWID had already used their annual allocations,
- Whether EBID or EPCWID already had sufficient supply to meet their irrigation demand, and
- Effects of the 2008 OA on how pumping impacts are distributed.

A comparison of the results of the crude redistribution performed by Ms. Moran to the results from the ILRG Model for the no Rincon-Mesilla pumping run (Run 6) is included in Section 30.0, and demonstrates the severe limitations of the crude Moran approach.

Moran Opinion 3 *- A second analysis using the Texas Model was made to evaluate the effects of a 60% reduction in total pumping (40% of the amount of pumping contained in the Texas Model's Historical model run) on Rio Grande flow and Project diversions. ("40% Pumping model run"). This model run was conducted with water budget and model files that were not available at the time of Stetson's May 31, 2019 report. The 40% Pumping model run further examines the Texas Model performance by making modifications to the WEL and SFR files, and comparing these results with the Historical and No Pumping model runs. The same methodology of model iterations performed for the No Pumping model run were applied to the 40% Pumping model run.*

Response:

Ms. Moran applied her crude redistribution process to the 40% pumping run of the Texas Model in which pumping was reduced by 60%. All of the criticisms described above for the No Pumping Run also apply to the 40% Pumping Run.

It is also important to point out the conceptual inconsistencies in the results of the 40% Pumping Run presented by Ms. Moran and the 40% Pumping Run presented by Dr. Hutchison.

Dr. Hutchison presented numerous simulations of alternative scenarios using the Texas Model in his May 2019 expert report. Among those runs was the 60% reduced pumping run (i.e., 40% Pumping Run). Dr. Hutchison identified this as a key run because it produced an average of 73,000 AF/y of Rio Grande flow at El Paso during 1951 – 2016 which he claimed was similar to the result of the double-mass curve analysis performed by Dr. Brandes that showed that the Rio Grande at El Paso flow had changed by an average of 79,000 AF/y during the same 1951-2016 period.

When Ms. Moran made a 40% Pumping Run of the Texas Model, she reported that it showed an average increase in Rio Grande flow at El Paso of 61,700 AF/y during 1951 – 2016, which is about 15% less than what Dr. Hutchison presented in his report. Then, when Ms. Moran applied her crude redistribution procedure to the 40% Pumping Run, the revised average annual increase in El Paso flow averaged only 26,800 AF/y. This is 63% less than the result presented by Dr. Hutchison, and 66% less than the result from the Brandes double-mass curve analysis. Notwithstanding all of the flaws in the crude redistribution by Ms. Moran described above, the results of her re-operated 40% Pumping Run appear to undercut the modeling results presented in the Hutchison expert report.

25.0 RESPONSE TO MORAN SECOND SUPPLEMENTAL REPORT

Ms. Jean Moran of Stetson Engineers, Inc. prepare a May 5, 2020 supplemental expert report on behalf of the United States ("Moran Second Supplemental Report") that included analyses and comparisons of the New Mexico ILRG Model and the Texas Model.

SWE was asked by legal counsel for New Mexico to review the Moran Second Supplemental Report and to prepare expert opinions to respond the opinions of Ms. Moran. A lack of response regarding a particular issue should not be interpreted as tacit agreement with the Moran opinions on that issue.

All of the criticisms of the Texas Model structure and inputs that are described in the SWE Report and elsewhere in the SWE Rebuttal Report also apply to the Texas Model runs described in the Moran Second Supplemental Report. The responses described below do not restate these criticisms but rather focus on particulars of the Texas Model runs performed by Ms. Moran.

The opinion numbering in this section picks up where the opinion numbering in the responses to the Moran Supplemental Report left off.

Moran Opinion 4 *- The ILRGM assumptions for the Baseline Run 1 appear to introduce noticeable differences (i.e. a pre/post 1985 bias) when compared to the Calibration Run 0 and gaged data. The assumptions that are part of the 'operational tuning' process should be reviewed to evaluate what causes these differences, and make the necessary improvements to either fix the observed differences or quantify the uncertainty that is introduced. (page 1).*

Response:

Ms. Moran points out differences in the performance of the ILRG Model before and after 1985. In particular, she highlights differences in simulated Caballo Reservoir releases (pre-1985: +2.5%; post-1985 -3.9%) and simulated El Paso flows (pre-1985: +3.6%; post-1985 -2.1%. Her summaries are based on comparison of model bias during 1940-1984 (pre-1985) and 1985-2017 (post-1985).

It is common for simulation models of complex system to vary in performance throughout a long study period. The bias (average % difference between modeled and measured values) for simulated Caballo releases and El Paso flows before and after 1985 fall within the within the "Very Good" performance evaluation criteria for PBIAS that are presented in Moriasi et al. (2015). These criteria are described in more detail in Section 28.0. Moreover, Ms. Moran presented no information or analysis to quantify the impact on model predictions that results from the small differences in average percent error before and after 1985.

Also noteworthy is that the differences between the pre- and post-1985 bias in the ILRG Model have narrowed for the Caballo releases and the Rio Grande at El Paso flows as summarized below.

Comparison of Pre- and Post-1985 PBIAS
Original (v106) and Updated (v116) ILRG Models

Output	ILRG Model (v106)	ILRG Model (v116)
Caballo Release		
Pre-1985 (1940-1984)	+2.5%	-0.9%
Post-1985 (1985-2017)	-3.9%	-0.7%
Total	-0.2%	-0.8%
Rio Grande at El Paso		
Pre-1985 (1940-1984)	+3.6%	-3.0%
Post-1985 (1985-2017)	-2.1%	2.3%
Total	1.2%	-0.6%

Moran Opinion 5 *- The mean absolute error ("MAE") for the annual differences in gaged and Baseline Run 1 simulated releases is 82,160 acre-feet/year (14% of average annual gaged releases). The root mean square error ("RMSE") for Caballo Dam gaged releases and Baseline Run 1 is larger, 110,900 acre-feet/year (18% error), because extra weight is given to larger differences. Both MAE and RMSE average errors indicate that some elements of the system are not captured correctly in the tuning process from Calibration Run 0 to Baseline Run 1. Further evaluation is warranted to determine the effects and uncertainties that are being introduced by the tuning process developed by the New Mexico experts for their Baseline Run 1. (page 7).*

Response:

As summarized in Section 28.0, the MAE and RMSE for annual Caballo releases in the updated ILRG Model are 47,600 AF/y and 58,100 AF/y, respectively. These values are significantly lower than the value that Ms. Moran computed for the prior version of the ILRG Model (version 106). All rule-based simulation models of complex system will produce results that do not exactly match historical values. The excellent overall performance of the updated ILRG Model is discussed at length in Section 28.0.

Moran Opinion 6 *- The RW Model manages the Caballo Reservoir more evenly than historical practices resulting in more spills in the late-1980s to mid-1990s indicated by the upper maximum reached on the monthly graph during this time period. The 'tuned' reservoir management does not appear to capture the historical variations that took place, and may contribute to the differences seen in the Caballo Dam releases (discussed in the previous paragraph). (page 8).*

Response:

Rules were added in the updated ILRG Model to increase reservoir releases and canal diversions in spill years. This improved the model performance during the wetter-than-average period of the 1980s and 1990s.

Moran Opinion 7 *- A comparison of the main canal diversions simulated in Baseline Run 1 (bottom graph, Figure 5) to the Calibration Run 0 (top graph, Figure 5) shows an average annual decrease of about 3% in diversions from 1951 to 2016, a period that coincides with increased groundwater pumping. The RW Model Baseline Run 1 shows an average of 11,800 acre-feet/year lower and the NMR-M Model shows an average of 13,200 acre-feet/year lower than the Calibration Run 0 for canal diversions. The RW Model estimates relatively consistent year-to-year canal diversions from 1984 through 2003 in the Baseline Run 1 that do not capture the variability observed during that same historical Calibration Run 0 time period. The Baseline Run 1 also underestimates the recent canal diversions in 2007-2008 and 2015-2017. The RW Model's 'tuned' Baseline Run 1 manages the canal diversions more evenly than historical practices (Calibration Run 0) resulting in overall decreased canal diversions compared with historical conditions that introduce some uncertainty into the predicted model results. The rule-based Baseline Run 1 underprediction of diversions from the river for the Rincon Mesilla Basins should be evaluated by the New Mexico experts to see if this introduces a bias in the proportioning of available Project water. (page 9).*

Response:

The average under-prediction of Rincon-Mesilla diversions by 11,800 AF/y in the ILRG Model described by Ms. Moran represents 3.0% of the Rincon-Mesilla diversions that average 400,000 AF/y. A 3.0% PBIAS qualifies as Very Good model performance under the criteria presented in Moriasi et al. (2015).

Moran Opinion 8 *- For the Baseline Run 1, on-farm surface water and groundwater required for meeting irrigation water demands are calculated by the RW Model for the ILRGM based on the 'tuned' rule-set developed to simulate historical conditions (Carron* *and Setzer, 2019). On average, the Baseline Run 1 FHG deliveries simulated by the RW Model (Table 4, Attachment B) are within 2,700 acre-feet/year of the FHG deliveries simulated in the Calibration Run 0 for the period 1951-2016. About 17% of the time (13 years),19 there is more than a 25% difference (± 45,000 acre-feet) in FHG deliveries between the Baseline Run 1 and the Calibration Run 0 (Figure 6 bottom graph). The MAE and RMSE for the annual differences between Calibration Run 0 and Baseline Run 1 FHG deliveries are 28,700 and 43,100 acre-feet/year, respectively, corresponding to 14% and 22% of the average annual historical FHG deliveries of 179,700 acre-feet/year. Both MAE and RMSE average errors indicate that that some elements of the system are not captured correctly in the tuning process from Calibration Run 0 to Baseline Run 1. Further evaluation should be undertaken by the New Mexico experts to determine the effects and uncertainties that are being introduced by the tuning process developed for their Baseline Run 1. (page 11).*

Response:

The simulated FHG deliveries in the ILRG Model represent the integration of the simulated Project operations, river operations, and canal system operations. Simulation of seasonal FHG deliveries are bound to be greater than measured in some years and less than measured in other years. The average underprediction in the simulated EBID and EPCWID FHG deliveries in the updated ILRG Model is less than 5% as shown in the results presented in Section 28.0. This qualifies as "Very Good" performance based on the PBIAS criteria presented in Moriasi et al. (2015).

Moran Opinion 9 *- Supplemental groundwater pumping for irrigation was initially estimated by Sullivan and Welsh (2019) for the ILRGM Calibration Run 0. The RW Model simulates about 7.3% (10,300 acre-feet/year) more irrigation pumping than the TX-RG Model (Table 5) during 1951 to 2016. The upper graph of Figure 7 shows the annual FHG deliveries of surface water and the supplemental pumping that make up the applied water simulated by the RW Model Calibration Run 0 and the TX-RG Model Calibration Run. Both the ILRGM and the TX-RG Model develop applied water based on crop irrigation requirements and on-farm efficiency assumptions. Figure 7 (upper graph) shows the annual differences in the two models – the RW Model calculates higher applied water than the TX-RG Model pre-1985, and lower applied water after 1985. (page 12).*

Response:

The pumping in the calibration run (Run 0) of the ILRG Model is computed by the on-farm simulation algorithm in the RiverWare Model. The results are very similar to but not exactly the same as the pumping computed in the SWE CFB Model and reported in the SWE Report.

Differences in the simulated Rincon-Mesilla pumping between the ILRG Model and the Texas Model are due to differences in (a) irrigated area, (b) crop irrigation water requirements, and (c) farm headgate deliveries. These differences are described in Section 12.0 of the SWE Report.

Moran Opinion 10 *- For the Calibration Run 0, the RW Model and NMR-M Model simulate streamflow out of the Mesilla Basin at the USGS streamflow gage 08364000 for Rio Grande at El Paso Narrows (Figure 1). When compared with the USGS gage 08362500 for Rio Grande below Caballo Dam, this streamflow data represents the net effect from hydrologic conditions, Rio Grande Project releases, canal diversions, seepage gains/losses, and return flows to the river within the Rincon and Mesilla Basins. The annual gaged and simulated data for these two USGS gages from 1940 to 2017 (model period) are shown in Figure 2 upper graph. For the Calibration Run 0, the RW Model simulates the long-term average Rio Grande gaged flows at El Paso Narrows almost exactly, and the NMR-M Model matches closely, within 300 acre-feet/year. The annual differences of Rio Grande flow at El Paso Narrows simulated by the RW Model compared with gaged data are shown on the upper graph of Figure 2, ranging from -74,600 acre-feet in 1979 to 96,300 acre-feet in 1948. The TX-RG Model was calibrated to the Rio Grande gaged flows at El Paso Narrows, and matches almost exactly as shown on Figure 2 upper graph. (page 15).*

Response:

The simulated flows in the updated ILRG Model for the Rio Grande at El Paso reasonably match the historical flows. This is reflected in the calibration statistics presented in **Table 28-1**. The exact match of the simulated and observed flows at the El Paso gage in the Texas Model is the result of inappropriate calibration techniques employed by Dr. Hutchison to adjust river bed conductance values and canal spills to drains in every stress-period to reproduce the historical gage flows (Barth, 2019).

Moran Opinion 11 *- New Mexico applied the ILRGM to ten different no-pumping scenarios by turning off groundwater production within different geographical areas (basins, states, country) or different entities (irrigation district, DCMI). The Rio Grande Project's operational criteria and farm processes developed for the Baseline Run 1 were applied to* *these different no-pumping conditions. In the absence of pumping, groundwater levels are higher, there are more gaining reaches in the river (and less river seepage (loss) to the aquifer), canals, and drains. This additional water in the river system becomes available for Project deliveries, affecting canal diversions and Caballo releases. The RW Model accounts for changes and feedback in Project operations and provides a new estimate of the surface water operations for assessing the impacts of pumping on Project supplies. The ILRGM's project re-operation was used to evaluate no-pumping scenarios where additional streamflow in the Rio Grande was allocated to both EBID in New Mexico and EPCWID in New Mexico and Texas based on the operational rules established in Baseline Run 1. (page 16).*

Response:

The changes and feedback in Project operations described by Ms. Moran in simulations of no-pumping scenarios and other scenarios are essential elements of the ILRG Model that simulate the real-world response of the Project operations to changes in conditions. This is one of many reasons that the ILRG Model is superior to Texas Model.

Moran Opinion 12 *- Two of the ILRGM model scenarios addressed no pumping in the Rincon and Mesilla Basins: Run 2 simulated no groundwater pumping in the Rincon, Mesilla, and Hueco Basins; and Run 6 simulated no groundwater pumping in the Rincon and Mesilla Basins with continued pumping in the Hueco Basin. This section of the supplemental report summarizes the effects of pumping in the Rincon and Mesilla Basins; compares the differences between the existing Run 2 and Run 6 simulated by the ILRGM (that also included linking the Hueco Model23); and compares these results with the TX-RG Model no-pumping results. Comparing the differences in Run 2 and Run 6 developed by New Mexico would show the effect of pumping in Hueco Basin on the conditions in the Rincon-Mesilla Basin. (page 16).*

Response:

Because of the non-linearities in the ILRG Model, it is not appropriate to compute the differences between Run 2 (All Pumping Off) and Run 6 (R-M Pumping Off) as a representation of the effects of pumping in the Hueco Bolson. The effects of Hueco pumping are more reasonably and accurately determined in a scenario in which the Hueco pumping is turned off by itself rather than differencing other model runs. See the discussion of the ILRG Model runs in Section 30.0

Moran Opinion 13 *- Stetson conducted an additional analysis using the RW Model and the NMR-M Model to evaluate the predicted effects of 40% pumping (60% reduction in Baseline Run 1 pumping) in the Rincon and Mesilla Basins in order to compare the RW Model predictions with a similar model run by Stetson using the TX-RG Model (Moran, 2019). The 40% R-M Pumping Run further evaluates the performance of the linked models and the ability to predict changes to Rio Grande Project operations (e.g. releases, diversions, deliveries) resulting from reduced pumping in the Rincon and Mesilla Basins. In addition, the changes to Rio Grande streamflow at El Paso Narrows and groundwater in storage are compared with the Baseline Run 1 and the TX-RG Model. (page 18).*

Response:

As discussed in the response to Moran Opinion 3, the 40% Pumping Run performed by Ms. Moran illuminate inconsistencies with the Texas Model runs presented in the Hutchison Report. Based on these inconsistencies, it is unclear what the purpose of the 40% Pumping Run is.

Moran Opinion 14 *- The RW Model input variables for No R-M Pumping Run 6 were adjusted for the 40% R-M Pumping Run. Agricultural and DCMI groundwater pumping variables were adjusted to account for 40% of the Baseline Run 1 pumping in the Rincon and Mesilla Basins. The corresponding variables for urban return flows to groundwater30 and wastewater treatment plan (WWTP) return flow to surface water were also adjusted to evaluate a 60% reduction in groundwater pumping used for the Baseline Run 1. There was one exception, the Las Cruces municipal WWTP return flow was adjusted to account for no changes to 10% of its water supply imported from outside of the basin. (page 19).*

Response:

When evaluating the effects of New Mexico pumping in the Rincon and Mesilla basins, WWTP returns that result from water imported from outside the basin should be turned off in order to compute an appropriate offset from that imported supply against the impacts of in-basin pumping. This includes turning off the return flows from Las Cruces use of imported water from its Jornada wells.

Moran Opinion 15 *- For the 40% R-M Pumping Run, the RW Model and NMR-M Model show about 9,200 acre-feet/year (1.5%) decrease in Project releases from Caballo Dam (Table 3) under reduced pumping conditions (Table 8). The RW Model and NMR-M Model simulated an average increase of Rio Grande streamflow at El Paso Narrows from 1951-2016 of 49,500 acre-feet/year and 49,700 acre-feet/year, respectively. The RW Model predicts a 7.6% (29,400 acre-feet/year) increase in canal diversions and an 11.2% (20,400* *acre-feet/year) increase in FHG deliveries under 40% Pumping Run conditions compared to Baseline Run 1 for 1951 through 2016. Figure 8 upper graph shows the cumulative change in groundwater storage, averaging -8,200 acre-feet/year (Table 9) under 40% pumping conditions. The Rio Grande streamflow at El Paso Narrows for the 40% Pumping Run shows a partial recovery over historical conditions (bottom graph of Figure 10). Stetson was not able to make any adjustments to Caballo releases in the TX-RG Model described in the first supplemental report (September 2019) – resulting in an increase of surface water for the Project. The proportioning method used by Stetson with the TX-RG Model estimated more canal diversions and farm deliveries, resulting in 26,800 acre-feet/year of streamflow at El Paso Narrows (Table 8). (page 21).*

Response:

The inability to adjust the releases from Caballo Reservoir in the 40% R-M Pumping Run of the Texas Model represents a fatal flaw in that model and a serious shortcoming in the crude proportioning method developed and applied by Ms. Moran to reallocate simulated increase in El Paso flows to upstream diversions in the Texas Model.

Moran Opinion 16 *- Both models are able to make predictions and show that pumping in the Rincon and Mesilla Basins impact the Project. Neither New Mexico nor Texas provided an error analyses for their models to give a range of uncertainty of the results. The differences between the models is likely within the uncertainty of the models. Both the New Mexico and Texas models are numerical tools showing that pumping impacts the Project and cutting back pumping would improve Project performance. Both models have uncertainties. (page 23).*

Response:

While both the ILRG Model and the Texas Model can be operated to simulate impacts from pumping in the Rincon and Mesilla Basins, shortcomings in the Texas Model that include (a) use of overly coarse annual stress periods, (b) a limited geographic scope that excludes simulation of the area between El Paso and Fort Quitman, and (c) no ability to reasonably re-operate the Rio Grande Project in response to changes in water supplies in alternative scenarios results in the Texas Model being far inferior to the ILRG Model.

26.0 LOWER RIO GRANDE DATA

26.1 Hydrologic Data

All hydrologic data opinions provided in Section 3.0 (Lower Rio Grande Hydrologic Data) of the SWE Report remain valid.

New Mexico has received limited additional hydrologic and water use data from Texas, the United States, and others since the SWE Report was submitted. These data include annual Socorro WWTP discharge data from 1967-1984 and monthly volumes of drain water diverted at Fabens to Tornillo Canal via the Riverside Canal Extension from 1945-1983. These additional data were added to the SWDataSet. Backup for these additional data are provided with this disclosure. An updated summary of the estimated data in the SWDataSet reflecting replacement of the previously estimated Socorro WWTP discharges with actual data is provided in **Table 26-1.**

The records for Socorro WWTP discharges and drain water diverted at Fabens were used as inputs to the updated ILRG Model.

26.2 Rio Grande Project Data

All Rio Grande Project accounting data, information, summaries, and opinions provided in Section 4.0 (Rio Grande Project Accounting Data) of the SWE Report remain valid.

New Mexico has received limited additional Project accounting data from the United States since the original SWE Report was submitted. These data, which include monthly accounting records 2008 – 2019 and Project allocation records for 2019, are currently under review.

27.0 LOWER RIO GRANDE CANAL AND FARM BUDGET MODELS

All data, information, and summaries provided in Section 6.0 (Lower River Grande Canal and Farm Budget Models) of the SWE Report remain valid, with the exception of the CFB Models for the Hueco area from 1903 – 1937 that were revised and updated. This included the CFB Models for the following geographic areas:

- EPCWID (El Paso Valley),
- HCCRD,
- JID Unit 1,
- JID Unit 2, and
- JID Unit 3.

The revisions to the annual CFB Models of the Hueco area are summarized below, and more detailed descriptions are provided in **Appendix 27**.

- The Water Distribution Report records of diversions and FHG deliveries for the El Paso Valley were used for the years they are available (1920, 1921, 1923, 1927, 1931, 1933, 1934, 1936, and 1937).
- A switch was added to turn off Juarez sewage discharge to canals when the Mexico pumping is turned off.

The revised annual CFB Models for the Hueco area were provided to MMA for generating the FHG delivery and on-farm deep percolation inputs to the Hueco GW Model.

28.0 OVERVIEW AND ASSESSMENT OF UPDATED ILRG MODEL

Several modifications were made by Hydros to improve the RiverWare Model (Hydros 2020). A summary of modifications is provided in Section 28.1 below. The assessments of the ILRG Model in Section 8.0 of the SWE Report remain valid except as modified by the descriptions in Section 28.2.

28.1 Revisions to RiverWare Model (v116)

Hydros made several revisions to the RiverWare Model to correct or improve the model functioning in operational mode when rules are used to simulate operation of the Project and the LRG irrigation systems. Many of the improvements result from responses to comments from the United States and Texas experts, questions during depositions, and further model review prompted by the United States and Texas comments. The following is a brief summary of the revisions:

<u>Model Changes</u>

- <u>Project Allocation Period</u> – Revise the pre-allocation period to end in 1949 and start the pre-D1/D2 period (during which the D1/D2 Rules are simulated) in 1950. While the Project Histories report that 1951 was the first year that an annual allotment was in effect for the entire irrigation season, allotments were issued in prior years that were lifted before the end of the season. Simulating annual allocations beginning in 1950 improved model tuning.

- <u>Maximum Annual Allocations to U.S Districts</u> – Compute time-series inputs of the maximum annual allocations for EBID and EP1 in full supply years using the D2 Curve, the maximum annual Project releases that were previously determined for 1955 – 1993, and a full supply allocation to Mexico of 60,000 AF. Compute the annual allocations to EBID and EP1 in RiverWare during 1955 – 1993 based on the D1/D2 procedure with allocations limited to maximum annual allocations. The annual allocation to Mexico is computed using the D1 Curve and the usable water in Project storage.
- <u>Final Annual Allocation</u> – Compute a final allocation to EBID and EPCWID in October for purposes of computing the amount of carryover when the D3 + Carryover rules are in effect.

- <u>Mexico Allocation</u> – Correct the computation of the annual allocation to Mexico during 1951 – 2017 as 11.3486% of the amount determined from the D1 Curve.

- Diversion Charge when One District Is Diverting – When only one District is diverting Project water, charge that District the maximum of its canal heading diversions or the Caballo Reservoir release minus the diversion by Mexico at the Acequia Madre.

- Project Water Split – Revise the split of Project water to be 57% for EBID and 43% for EPCWID during the period from 1955-1979 rather than the 60%/40% split that was previously used.

- Reservoir Threshold Elevations – Revise the elevations in Elephant Butte Reservoir and Caballo Reservoir above which spills and flood control operations are simulated.

- Reservoir Operations in Spill Years – Increase the EBID and EPCWID waste percentages during reservoir spill years. The added waste is routed through the EBID and EPCWID systems without being charged against their allocations.

- Net Losses in Elephant Butte Reservoir to Caballo Reservoir Reach – Release water from Elephant Butte Reservoir to cover net losses in the Elephant Butte Reservoir to Caballo Reservoir reach.

- Reservoir Evaporation Estimate for D1/D2 Allocation – Revise the estimated monthly evaporation values for Elephant Butte and Caballo Reservoirs used in computing the total usable water in D1/D2 allocation to be the average of years when Project storage is at or below a full supply of approximately 790,000 acre-feet.

- Pre-1950 Caballo Reservoir Winter Releases – Simulate releases from Caballo Reservoir during the winter months before 1950 consistent with historical operation.

- ACE Credit – Revise the application of the ACE credit to be simulated only in the years that it was historically applied.

- EP1 Use of Fabens Drain Flows – Simulate historical use of Fabens drain flows by EP1 based on historical records (1945 - 1983) in historical Base Run and all alternative scenarios (except scenarios with increased use of Fabens drain flows).

- EPCWID Orders – Adjust EPCWID Orders for EPW WWTP discharges and use of Fabens drain flows. Revise the equation for computing EPCWID orders of Project water at American Dam by subtracting the EPW WWTP discharges to canals (Haskell, Bustamante, and Socorro) and the use of Fabens drain flows.

- EPCWID Waste – Revise EPCWID waste to be computed as specified percentages of canal heading diversions rather than bypass of a portion of the deliveries to certain EPCWID subareas.

- EPCWID Diversion Charges – Add the simulated canal loss in the Texas Mesilla from the NMR-M Model to the EP1 Mesilla diversion charges rather than charging EBID for all Mesilla canal losses. Credit EBID for 1.15 x revised EP1 Westside Canal diversion charges and 1.20 x revised Eastside Canal diversion charges.

- EPCWID Diversion Charges Option – Add an option to charge EPCWID for use of drain flows and WWTP discharges. This option is enacted in several of the new alternative scenario runs described in Section 30.0.

- Distribution of Irrigation Water in EPCWID – Improve the distribution of water to EPCWID subareas to be more proportionate to irrigated area instead of distributing water top to bottom based with specified bypass percentages.

- Riverside Waste to Tornillo Drain – Add a rule to compute waste discharge from the Riverside Canal to the Tornillo drain based on monthly percentages computed from historical records.

- Hudspeth Feeder Canal Diversions – Add two rules to manage flows in the Hudspeth Feeder Canal. The first rule routes Fabens Waste Channel flows in excess of the historical Hudspeth Feeder Canal diversions to the Rio Grande. The second rule diverts water from the Rio Grande to the extent the Fabens Waste Channel flows are less than the historical Hudspeth Feeder Canal diversions.

- River Headgate Demand - Rearrange the equation that computes the river headgate demands so that the tuning factor is only applied to the crop, soil moisture, and EPW demands, and not to the conveyance losses and EPCWID use of WWTP discharges and drain flows.

- EPCWID Allocation Limit - Adjust the rule that limits EPCWID diversions when the EPCWID has less remaining allocation than demand.

- EPCWID FHG Deliveries – Add river seepage as an independent term in the equation that computes the EPCWID farm headgate deliveries.

- ACE Credit – Revise the rule that computes the ACE Credit to use the equation that has historically been most frequently used in the Project accounting.

Data Changes

- Haskell WWTP Discharges – Specify the Haskell WWTP discharges to the Franklin Canal and the Rio Grande based on historical records.
- Socorro WWTP Discharges – Use historical Socorro WWTP discharge data that was recently provided by Texas and the United States instead of the estimates of WWTP discharge that were used.
- Hueco WWTP Return Flows Attributed to Project Water – Set the time series input of WWTP discharges attributed to Project water to zero during the non-irrigation season. This avoids simulating WWTP discharges of Project water during the non-irrigation season when Project water deliveries are not simulated.
- EPW Hueco WTP Diversions – Compute monthly EPW water treatment plant diversions computed by multiplying the simulated monthly EPCWID allocations by a time series of monthly percentages input to the model. The monthly time-series percentages were recomputed as historical monthly EPW WTP diversions divided by the simulated monthly EPCWID allocations in Run 1 of the ILRG Model.
- Rincon and Mesilla Valley Canal Capacities – Reduce the simulated capacity of the Rincon, Leasburg, Eastside, and Westside canals to limit the simulated maximum monthly diversions consistent with historical diversion records.

The revisions to the RiverWare Model rules and data described above resulted in some minor changes to the Calibration Run (Run 0), but not enough to require the model to be recalibrated. However, the model changes did necessitate that the model be retuned so that the simulated reservoir operations and deliveries of Project water in the Historical Base Run (Run 1) reasonably matched historical records or in some cases, simulated values in the historical Calibration Run (Run 0) (e.g., simulated irrigation pumping). Comparisons of the revised Historical Base Run (Run 1) against historical data and simulated results from the Historical Calibration Run (Run 0) are presented in the figures and tables that are described below. As evidenced in these figures and tables, the revisions to the RiverWare Model rules and input data described above and the subsequent retuning have improved the ILRG Model and the correspondence between simulated flows in the Historical Base Run (Run 1) and the historical observed data (and in some cases to the simulated outputs from Run 0). This is particularly evident in the simulated reservoir storage, reservoir releases, Project water diversions and FHG deliveries, and El Paso flows. Based on these model enhancements and improved model performance, the revised ILRG Model continues to be the best available tool to simulate the effects of pumping and changes in Project operations on the supplies available to LRG water users.

28.2 Summary of Updated ILRG Model Tuning

In response to criticisms in the rebuttal and supplement expert reports by Texas experts Shane Coors and George Hornberger, additional charts and tables were prepared to present and summarize the calibration and tuning of the updated ILRG Model.

As discussed in the SWE Report, development of the ILRG Model included a physical calibration process in which monthly Caballo releases, diversions, and FHG deliveries were set to historical records (and estimates), and physical parameters in the models including aquifer hydraulic conductivity, river bed conductance, canal bed conductance, and drain bed conductance were adjusted to improve the match between modeled outputs, and observed data for river flows, drain flows, and ground water levels.

After the physical calibration of the ILRG Model, the historical records specifying the Caballo releases, diversions, and FHG deliveries were replaced by operational rules that operate the Project and LRG irrigation systems. The operational rules were tuned to match simulated reservoir releases, diversions, and FHG deliveries to the historical data. The match of historical drain flows and river flows was also reviewed during the tuning process.

After making the changes to the ILRG Model that are discussed in Section 28.0, it was necessary to retune the model. The tuning of the model was evaluated using various statistical and graphical performance measures recommended for use in assessing calibration of hydrological models. Unless otherwise specified, the term “calibration” as used below refers to the goodness of fit between the simulated outputs of the calibrated and tuned ILRG Model and the historical data.

While there is no universal consensus in the scientific community for evaluating the calibration of hydrologic models, a recent article by Moriasi et al. (2015) contains proposed guidelines for model performance evaluation based on meta-data analysis of hydrologic models reported in numerous peer-reviewed journal articles since 1990. This article synthesizes the recent state of the art of model calibration assessment and was used as a general guide for selection of the performance measures used for evaluating the calibration of the updated ILRG Model. The following subsections describe and present these statistical and graphical performance measures.

28.2.1 Statistical Performance Measures

Statistical performance measures provide an objective and reproducible process for evaluating model calibration. Moriasi et al. (2015) recommends use of the following statistics to assess the model calibration performance each of which have advantages and disadvantages, but together provide a reasonable and comprehensive picture of model calibration.

- Coefficient of Determination (R2) – Degree of collinearity between modeled and measured data.
- Nash-Sutcliff Efficiency (NSE, E2) – Relative magnitude of the residual variance compared to the measured data variance.
- Index of Agreement (d2) – Ratio between the mean square error and the potential error represented by the largest value that the squared difference of each measured and observed data pair can attain.
- Root-Mean Squared Error (RMSE) – Square root of the mean square error.
- RMSE-Observed Standard Deviation Ratio (RSR) – RMSE normalized using the standard deviation of the observed data.
- Mean Error or Bias (BIAS) – Average of the positive and negative differences between the modeled and measured data.
- Percent Bias (PBIAS) – Mean error expressed as a percentage of the average of the observed values.
- Mean Absolute Error (MAE) – Average of the absolute value of the differences between modeled and observed values.
- Percent MAE (PMAE) – Mean absolute error expressed as a percentage of the average of the observed values.

Descriptions of the equations, range of possible values, optimal values, and advantages and disadvantages of the above statistics is provided in Table 5 of the Moriasi et al. (2015) article which is included in **Appendix 28**.

In addition to the statistics listed above, **Table 28-1** also includes results for the Log NSE statistic that was advocated by Mr. Coors. As discussed in Section 23.0, the Log NSE statistic is inappropriate for evaluating the calibration of the ILRG Model because of how it inappropriately weights differences in low flows. Nevertheless, the Log NSE statistic is included in **Table 28-1** for comparison to the results presented in the Coors Supplemental Report.

The spatial and temporal scales of the input data, calibration data, model processes, model outputs, and the intended model uses need to be considered in determining how to apply the calibration statistics to the model output. To achieve meaningful results, model performance assessment must focus on the processes and model outputs that are relevant to the model purpose using methods that reflect variation at the appropriate temporal and spatial scales (Baffaut, 2015).

Most of the inputs, outputs, and simulation processes of the ILRG Model are monthly, consistent with the monthly stress periods of the model. However, the model results should generally be assessed as irrigation season or annual totals. For example, when comparing the results of a no pumping run against the Historical Base Run (Run 1), differences between model outputs can be computed at monthly or longer time intervals. However, it makes little sense to evaluate simulated changes in Project water deliveries at monthly intervals because water users generally have wide latitude for ordering and receiving delivery of water most anytime within the irrigation season (subject of course to orders being bunched in water short years to minimize transit losses). Of more significance are the differences between model runs of diversions and deliveries over the entire irrigation season. Consistent with this, it is appropriate that the calibration of the ILRG Model also be evaluated based on irrigation season totals rather than monthly totals.

The spatial resolution of the model calibration assessment should be consistent with the resolution of the input data, calibration targets, modelled processes, and model linkages. As shown in **Table 23-1** in the response to the Coors Supplemental Report in Section 23.0, the spatial resolution of LRG data that are either used in the model or available for calibration assessment include point, valley, district, and basin scale information. The coarse nature of some of the input data (valley, district, basin) result in some level of smoothing of model inputs. Therefore, while farm budget calculations in the model are performed at a sub-area scale to spatially distribute model processes, it is not reasonable to assess certain of the model outputs on a fine spatial scale that is inconsistent with the model inputs. A prime example is the assessment of drain flow calibration. While drain flow data (measurements and estimates) are reported for some individual canals, it is unrealistic to expect the model to calibrate well to individual drains. Further, since the flow of many drains return flows that comingle upstream of where the next downstream diversion occurs it is reasonable to aggregate the flow of such drains for calibration assessment.

The simulation period of the ILRG Model extends from 1940 – 2017. However, widespread irrigation pumping did not commence until the late 1940s and early 1950s. In addition, the 1940s were characterized by greater than average inflows to Elephant Butte Reservoir and plentiful Project storage resulting in little restriction on use of Project water, and water users generally had sufficient supplies to meet demands. Therefore, consistent with the prior calibration and tuning described in the original reports of the New Mexico experts, calibration of the updated ILRG Model was evaluated primarily for the period from 1951 – 2017. The beginning of the calibration assessment period generally coincides with initiation of widespread irrigation pumping in the LRG area and also overlaps the 1951 – 1978 period from which data were used to develop the D1 and D2 curves that were subsequently used for allocation of Project water to the U.S Districts and Mexico.

Statistics summarizing calibration of the ILRG Model over the 1951 – 2017 period are tabulated in **Table 28-1**. Certain of these statistics were evaluated against Performance Evaluation Criteria presented in Moriasi et al. (2015) for R2, NSE, d, and PBIAS. These criteria characterize the model performance based on the value of the computed statistic relative to numerical ranges that define performance as Very Good, Good, Satisfactory, Not Satisfactory, and Unacceptable. The performance ranges for each statistic are listed in the color-coded legend at the bottom of **Table 28-1**. Note that no criteria were reported in Moriasi et al. (2015) for RMSE, RSR, and PMAE.

The ILRG Model performance summarized in **Table 28-1** ranges from satisfactory to very good for most of the calibration statistics when the results are appropriately evaluated using irrigation season totals. The improvements and re-tuning have generally elevated the statistical performance of the updated ILRG Model over that of the ILRG Model (v. 106) that was presented in the original reports of the New Mexico experts.

28.2.2 Graphical Performance Measures

Performance of the ILRG Model in simulating historical conditions was also evaluated using various graphical performance measures including monthly and annual time series plots, cumulative plots, scatter diagrams, and flow duration curves. These graphs facilitate qualitative assessment of the model capability to reproduce historical patterns and trends in the model output in a manner that the statistical measures do not. **Figure 28-1** through **Figure 28-21** present the graphs for each of the individual and aggregated locations for which calibration statistics are presented in **Table 28-1**.

The monthly and yearly time-series graphs show that the ILRG Model generally performs well in matching the monthly, seasonal, annual, and decadal patterns and variability present in the historical data.

- Caballo Release (Figure 28-1) – Monthly and annual releases match very well throughout the study period as evidenced by the monthly and annual time-series plot and the cumulative residual graph. Modeled annual releases match the historical records throughout the range of simulated values as indicated in the scatter plot and flow duration curve.

- Rio Grande at El Paso (Figure 28-2) – Monthly and annual flows match very well throughout the study period as shown in the monthly and annual time-series plot and the cumulative residual graph. The peaks and troughs of the simulated flows agree in most years indicating the supplies delivered during the irrigation season and return flows in the non-irrigation season are well simulated. Modeled annual flows match the historical records throughout the range of simulated values as indicated in the scatter plot and flow duration curve.

- Rio Grande at Fort Quitman (Figure 28-3) – Differences in simulated and measured flows at Fort Quitman represent the accumulation of all imperfections in the model simulation. While the variability of the monthly flows is not well matched, the annual and multi-year trends in flow are well simulated. The cumulative residual graph shows a general overprediction of flows in the 1940s and an underprediction of flows in the 1970s and 1980s. The horizontal slope of the cumulative residual line from about 1950-1970 and after 1990 shows the model replicates the annual flows reasonably well during these periods.

- Rincon and Mesilla Valley Diversions (Figures 28-4 – 28-7) – Irrigation season diversions are generally simulated well throughout the study period, aside from some overprediction for the smaller Rincon and Eastside Canals in the 1940s. The good match is evidenced in the irrigation season time-series graphs and the cumulative residual graphs that are relatively flat after the 1940s. The monthly diversion patterns are reasonably replicated in most years although there is some tendency to overpredict peak month diversions in full supply years.

- El Paso Valley Diversions (Figures 28-8 – 28-12) – Diversions at American Dam, Acequia Madre, Riverside Canal Gage, Franklin Canal Gage, and Total HCCRD Supply are generally simulated well after some underprediction in the 1940s as indicated in the monthly and annual time-series graphs. The cumulative residual graphs show no unreasonable long-term over- or under-predictions of diversions. The patterns of monthly diversions are simulated well, including monthly peak diversions.

- EBID FHG Deliveries (Figure 28-13) – Deliveries are typically simulated well, matching the yearly variability and long-term trends. Peak monthly flows tend to be overpredicted in full supply years, but the overall monthly patterns of deliveries match well.

- <u>EPCWID FHG Deliveries (Figure 28-14)</u> – There is a slight tendency toward underprediction of deliveries, particularly in wet years. The monthly pattern of deliveries is well matched.

- <u>HCCRD FHG Deliveries (Figure 28-15)</u> – The yearly and long-term trends in deliveries are satisfactorily simulated. The cumulative residual charts demonstrate a tendency toward overprediction of deliveries before 1980 and underprediction of deliveries after 1980.

- <u>EBID Pumping (Figure 28-16)</u> – Accurate simulation of supplemental pumping in the ILRG Model reflects a culmination of the successful simulation of the physical and operational processes that ultimately deliver inflows to Project storage to the end users. Given the complex interaction of all of the modeled processes, the replication of the pumping volumes in the yearly time-series plot is outstanding. As is the relatively lack of wavering in the cumulative residual chart and the degree of agreement throughout the range of pumping in the flow duration curve.

- <u>EPCWID Pumping (Figure 28-17)</u> – Supplemental pumping is simulated almost as well as for EBID with some underprediction late in the study period. The flow duration curve demonstrates pumping is generally well matched in all hydrologic conditions.

- <u>HCCRD Pumping (Figure 28-18)</u> – Supplemental pumping tends to be underpredicted in most years.

- <u>Rincon Valley Drains (Figure 28-19)</u> – Good simulation of drain flows is difficult because it requires reasonable simulation of ground water elevations (and surface water elevations) and the processes that conduct and attenuate the drain flow responses to the simulated elevation differences. Given these challenges, the ILRG Model simulates acceptable responses of the Rincon Valley Drains throughout the study period with some underprediction of flows until about 1980. The amplitude of the monthly variations in the simulated drain flows is satisfactory. The historical data for the Rincon drains are substantially incomplete after 2002 and therefore there is no observed data shown in the graphs after that time.

- <u>Mesilla Valley Drains (Figure 28-20)</u> – The Mesilla Valley drains, which transmit roughly five times as much flow as the Rincon Valley Drains are simulated very well in the ILRG Model. The annual flows are well matched throughout the study period as shown in the annual time-series plot, the cumulative residual plot, and the flow duration plot. The seasonal amplitude of the monthly flows is also well matched during most years. The historical data for the Mesilla Valley drains are substantially incomplete after 2013 and therefore there is no observed data shown in the graphs after that time.

- El Paso Valley Drains (Figure 28-21) – El Paso Valley drains are simulated generally well as shown in the annual time-series and cumulative residual plots, except for some underprediction of flows from 1960-1980. The amplitude of the monthly flow variations tends to be underpredicted in most years before 1990, but well matched thereafter.

28.2.3 Summary and Conclusions

Given the complexity of the Rio Grande Project area and the need to simulate the mix of physical and management processes that characterize the Project operations, the overall calibration performance of the ILRG Model is remarkable. In my opinion the superior calibration performance of the ILRG Model that is achieved using rational process-based rules clearly demonstrates that the updated ILRG Model is suitable for use in evaluating the claims and counterclaims in this case.

While the overall calibration performance of the ILRG Model is excellent for a system as complex as the Rio Grande Project and the associated portions of the LRG Basin, the model performance in matching the historical flows in the Historical Base Run (Run 1) is not perfect. It is important to understand that the imperfections in the Historical Base Run do not carry over into computed differences between the Historical Base Run and alternative scenario runs. This is due to the cancelling of errors that occurs when differencing model runs. For example, when the flow at El Paso or the diversion at the American Canal are overpredicted in a particular month in the Historical Base Run, that error will tend to also be present in the alternative run. Therefore, when the differences between model runs are computed, these errors will cancel out. The resulting computed differences then reflect the change in stress or operating rules between the two runs.

Canceling of errors is clearly evident in careful review of the differences between model runs. The simulated changes in flows such as streamflows, diversions and deliveries are reasonable and consistent with differences in the model inputs for the two runs and the simulated processes in the ILRG Model. In detailed review of the model results, there have been no identified differences between runs that could not be attributed to the rational functioning of the model rules. The cancelling of errors is why even relatively small differences between runs are reasonable and rational and are not lost in the noise of random errors that do not cancel out.

The ILRG Model is clearly more capable than the Texas Model of simulating the response of Project operations to changes in conditions simulated in alternative scenarios than is the Texas Model. The serious shortcomings of the Texas Model, which include rudimentary annual stress periods that foreclose the model from distinguishing between irrigation season and non-irrigation season flows, absence of dynamic simulation of Project operations that can respond to changes in flows and stresses in alternative scenarios, and limited geographical scope that excludes simulation of Project operations and water use downstream of the El Paso gage, render the Texas Model of limited or no utility in analyzing the complex issues that are presented in this case.

29.0 HISTORICAL BASE RUN OF ILRG MODEL

As described in Section 28.0, a number of revisions were made to the RiverWare Model to refine the simulated Project operations and water distribution. After these revisions were made the model was retuned and iterated with the ground water models to closure to produce a revised Historical Base Run (Run 1). Various water budget summaries and other outputs for the original Run 1 were presented in figures discussed in Section 9.0 of the SWE Report. Updated versions of those figures for the new Run 1 are included as **Figure 29-1** through **Figure 29-10** and a new **Figure 29-11** as listed below:

- Annual Reservoir Budget Summaries (**Figure 29-1**)
- Annual Project Allocations and Charges (**Figure 29-2**)
- Annual Canal and Farm Budget Summaries (**Figure 29-3** – **Figure 29-6**)
- Annual River Budget Summaries (**Figure 29-7** – **Figure 29-8**)
- Rio Grande Flow Summaries (**Figure 29-9** – **Figure 29-11**)

The illustrations of the Historical Base Run (Run 1) outputs provided **Figure 29-1** – **Figure 29-10** are similar to the comparable figures in Section 9.0 of the SWE Report. The detailed discussions of the Section 9.0 figures in the SWE Report also are applicable to the updated figures in this report. These summaries of the Historical Base Run along with the calibration results described in Section 28.0 show that the ILRG Model reasonably simulates the operations of the Rio Grande Project and the irrigation systems of the LRG Basin.

30.0 ALTERNATIVE RUNS OF ILRG MODEL

The updated ILRG Model (v116) was used to re-run the no-pumping scenarios and operations scenarios that were presented in the SWE Report (Runs 2 – 13). A list of the original model runs is provided in **Table 30-1**.

In addition to re-running the original 13 scenarios, the updated ILRG Model was used to simulate additional no-pumping scenarios and operations scenarios. These included Run 14 and several variants that simulate the effects of pumping in the Hueco and Run 15 and several variants that simulate early EPCWID operations prior to changes in water use practices. In addition, five other scenarios were simulated (Runs 16, 16a, 17, 17a, and 18) to analyze conjunctive use of surface water and ground water. These conjunctive use scenarios are based on either a D1/D2 level of supplemental pumping or a supplemental pumping level up to the crop demands on the authorized Project acres, and were developed in consultation with representatives and legal counsel for New Mexico. A list of the additional model runs is provided in **Table 30-2**. Additional specifications for the model runs are provided in **Appendix 30-A** including details for Runs 15-18 and details for the WWTP discharges and urban deep percolation returns that are turned off or reduced in certain of the alternative scenarios.

The results from the re-running of the original scenarios and simulation of the new scenarios are presented in a consistent format in the tables and graphs in **Appendix 30**. These include tabular and graphical results similar to those presented in the SWE Report as well as several additional tables and graphs. Unless otherwise noted, all of the results presented in **Appendix 30** are comparisons between an alternative scenario and the Historical Base Run (Run 1). There are 22 pages of tables and graphs included in the run comparisons for each scenario. An overview of the format and content of each of these tables and graphs follows:

- <u>Cover Page (p. 1)</u> – Selected input specifications for the two runs being compared.

- <u>Comparison of ILRG Model Runs (p. 2-3)</u> – This two-page table provides a high-level overview of how the ILRG Model distributes the change in inputs (e.g., change in pumping stress or change in operating rules) into changes in model outputs. The first five rows of values are the average annual pumping stresses in each run, which consist of the irrigation pumping that is on in Run 1 and off in the alternative run, and the total non-irrigation pumping and non-irrigation pumping return flows (WWTP discharges and urban deep percolation). The Total Stress is computed as the sum of the irrigation and non-irrigation pumping less the non-irrigation returns flows. The third column of numbers shows the difference in stress between the two runs being compared. The remainder of the table reports the annual averages for selected ILRG Model outputs and the differences in outputs between the two runs. The fourth and fifth columns of numbers express the average annual output differences as percentages of the change in Total Stress and as percentages of the Base Run values. For the alternative runs that simulate differences in operating rules (i.e. Runs 11-13, 15-18), there are no rows in the table listing the stresses, nor is there a column listing the % Change Stress.

- Annual Differences in ILRG Model Outputs (p. 4-5) – This two-page table lists the differences in model outputs for selected model outputs. These include the differences in irrigation season and annual net RHG Diversions and FHG Deliveries, and differences in annual river flows at the Caballo outlet, El Paso, and Fort Quitman. Net RHG Diversions are defined as the simulated gross diversions less the historical El Paso carriage water that was delivered through the Rincon and Mesilla Valley canals and less the simulated flood control releases that were run through the canals in spill years. Reporting of differences in net RHG Diversions in the model results represents a change from the reporting of differences in gross RHG diversions that were presented in model results described in the SWE Report.

- Simulated Differences in ILRG Model Outputs (p. 6-9) – These four pages of graphs and tables show differences in model outputs expressed as either annual or irrigation season totals. There is a bar chart with the yearly differences in model output, an inset line chart showing the annual outputs that are differenced in the bar chart, and a table summarizing the yearly average differences (annual or irrigation season totals). The differences in net RHG diversions and FHG deliveries are shown in line graphs rather than bar charts.

- Annual Allocation and Charges (p. 10) – This chart summarizes for the two compared runs the simulated annual allocation and delivery charges for EBID and EPCWID, as well as the simulated annual Diversion Ratio computed as the sum of the annual diversion charges for EBID, EPCWID, and Mexico divided by the annual Caballo Reservoir releases.

- Annual Summary of Project Storage and Rio Grande Flows (p. 11) – This chart summarizes for the two compared runs the total year-end project storage in Elephant Butte and Caballo Reservoirs and the annual Rio Grande flow at the Caballo Reservoir outlet, at El Paso, and at Fort Quitman.

- Irrigation Season Summary of Irrigation Operations (p. 12-14) – These three pages of charts summarize for the two compared runs the net RHG diversions, FHG deliveries, irrigation pumping, and RHG diversions minus FHG deliveries (conveyance losses). There are separate pages for EBID, EPCWID, and HCCRD.

- Cumulative Change in Ground Water Storage (p. 15) – This chart summarizes for the two compared runs the cumulative year-end change in ground water storage in the alluvial and non-alluvial aquifers in the Rincon and Mesilla valleys and in the Hueco.

- Monthly Net RHG Diversions (p. 16-18) – These three pages of charts show for the two compared runs the simulated monthly net RHG diversions. There are charts showing the total EBID diversions, total EPCWID diversion, and the total flow to HCCRD.

- End of Month Reservoir Storage (Elephant Butte + Caballo) (p. 19) – This chart shows for the two compared runs the combined end-of-month Project storage in Elephant Butte and Caballo Reservoirs. This doesn't include storage of non-Project water.

- Monthly Rio Grande Flows (p. 20-22) – These three pages of charts show for the two compared runs the simulated monthly Rio Grande flows at the Caballo Reservoir outlet, at El Paso, and at Fort Quitman.

Narrative summaries of the ILRG Model simulations of alternative scenarios are provided below to highlight and explain some of the more significant results shown in the tabular and graphical summaries presented in **Appendix 30**. The tables in **Appendix 30** include annual and irrigation season differences in model outputs for all run comparisons. Averages are computed for the following noteworthy ranges of years:

1951-2017: Period with irrigation pumping development commencing with the beginning of the D1/D2 data period (57/43 allocation until 2006).

1951-1978: D1/D2 data period (57/43 allocation).

1979-2005: Post D1/D2 data period prior to the 2008 OA allocation and accounting that commenced in 2006 (57/43 allocation).

2006-2017: Period when the 2008 OA allocation and accounting was in effect (D3 allocation for 2006 and 2007, D3 allocation plus carryover for 2008-2017).

1985-2017: Period for which alleged damages were computed by Texas (1985-2016) plus the last year of the study period (2017).

1985-2005: Portion of the Texas damages period prior to commencement of the 2008 OA allocation and accounting.

Averages for other portions of the study periods can be computed from the data in the run comparison spreadsheets that are being disclosed with this report.

30.1 All Pumping Off (Run 2)

In Run 2, all irrigation and non-irrigation pumping in the study area is turned off, and all non-irrigation returns, including WWTP discharges and urban deep percolation returns, are also turned off. The changes in irrigation returns that result from turning off the irrigation pumping are simulated by the farm budget processes included in the model.

The ILRG Model re-operates the Project and all of the simulated irrigation systems in the absence of pumping. Turning off pumping increases drain flows and reduces river seepage in most years. During full allocation years, this results in water accumulating in storage as less water needs to be released to meet demands. Accumulating water in storage increases allocations and Caballo Reservoir releases in subsequent dry years (e.g., several years in the 1960s, 1970s, and 2000s). Spills are also larger due to the accumulated water in storage.

The increased allocations result in increased diversions and FHG deliveries to EBID in dry years between 1950 and 1978. During the full allocation years from 1979 – 2002, there is little change in EBID diversions, however FHG deliveries increase modestly due to reductions in the simulated canal conveyance losses in the no-pumping run that allowed more of the water that is diverted to be delivered to the farms. When dry conditions return, EBID diversions and FHG deliveries increase again in 2003 and 2004. EBID diversions increase substantially beginning in 2006 due to the effects that pumping has when the 2008 OA is in effect. As is discussed in Barroll (2019), EBID's allocation under the 2008 OA is sensitive to the diversion ratio. When pumping is turned off, the diversion ratio increases resulting in increased allocations and increased deliveries to EBID. On average from 2006 – 2017, EBID's diversions increase by 148,700 AF and FHG deliveries increase by 92,700 AF.

The increase in Project water allocations also results in increased diversions and FHG deliveries to EPCWID in many dry years in the 1950s – 1970s. There are also modest increases in EPCWID diversions during many full allocation years in the 1980s and 1990s because the reduction in EPW WWTP discharges to EPCWID canals results in EPCWID requiring more reservoir releases to meet its demands. Increases in deliveries also occur in several dry years in the 2000s – 2010s although the increases are not near as large under the 2008 OA after 2005 as they are for EBID.

Turning off pumping and the resulting effects on Project operations and deliveries results in increased Rio Grande at El Paso flow in most years averaging 79,000 AF annually during 1951 – 2017. Of this amount, an average of only 33,100 AF occurs during the irrigation season (Mar-Oct) and the remaining 45,900 AF occurs during the non-irrigation season (Nov-Feb) or during reservoirs spill. During the 1985-2005 period, the increase in irrigation season flows, excluding spills, averages 15,700 AF. A portion of the increase is attributable to turning off New Mexico pumping and a portion is due to turning off Texas pumping. Cessation of pumping also produces substantial increases in flow at Fort Quitman averaging 100,300 AF annually during 1951-2017.

30.2 NM Pumping Off (Run 3)

In Run 3, all irrigation pumping and all non-irrigation pumping and returns in New Mexico is turned off. This includes all EBID supplemental irrigation pumping, all primary irrigation pumping in the Rincon Valley and Mesilla Valley, and all non-irrigation pumping and associated WWTP discharges and deep percolation returns in New Mexico.

Many of the simulated effects of turning off New Mexico pumping are similar to but smaller than the effects of turning off all pumping in Run 2. There is a similar pattern of accumulations in Project storage that are released in dry years when the simulated Project allocations increase. The accumulated storage again leads to larger spills.

EBID diversions increase by an average of 46,300 AF during 1951-2017, while FHG deliveries increase by an average of 31,200 AF. When the 2008 OA is in effect during 2006-2017, turning off New Mexico pumping increases EBID diversions by an average of 137,500 AF, and FHG deliveries increase by an average of 83,900 AF.

The impacts of New Mexico pumping on EPCWID supply are less than the impacts on EBID. From 1951 – 2017, EPCWID irrigation season diversions increase by an average of 18,500 AF and FHG deliveries increase by an average of 11,700 AF. After 1984 when Texas is claiming damages, New Mexico pumping impacts EPCWID irrigation season diversions by an average of 17,200 AF and irrigation season FHG deliveries by an average of 9,700 AF (1985-2017). During 1985-2005, prior to implementation of the 2008 OA, EPCWID irrigation season diversions increase by an average of 10,900 AF and irrigation season FHG deliveries increase by an average of 5,100 AF.

Simulated flows in the Rio Grande at El Paso increase when New Mexico pumping is turned off by an average of 61,100 AF annually during 1951-2017, of which an average of 22,900 AF occurs during the irrigation season and 38,200 AF occurs during the non-irrigation season or during spills. Average annual flows at Fort Quitman during 1951-2017 increase by an average of 49,000 AF due largely to return flows from increased surface water deliveries and reduced surface water depletions from pumping. This run shows that the Texas Model without reoperation greatly exaggerates the impacts of New Mexico pumping on El Paso flows.

30.3 TX Pumping Off (Run 4)

In Run 4, all supplemental irrigation pumping in EPCWID and HCCRD is turned off, as is all non-irrigation pumping and associated returns in the Texas portion of the Mesilla Valley and in the El Paso Valley. Deliveries of Project water to EPW and the associated return flows continue to be simulated in Run 4.

When Texas pumping is turned off, annual EBID diversions increase by an average of 5,400 AF/y during 1951-1978, and by an average of 15,500 AF during 2006-2017 when the 2008 OA is in effect. The impacts of Texas pumping are magnified by the sensitivity of changes in the diversion ratio on EBID allocations. The pattern of impacts on EBID FHG deliveries is similar with impacts to diversions that average 4,300 AF during 1951-1978 and 9,600 AF during 2006-2017.

Texas pumping also impacts Project water deliveries to EPCWID. The net effect on EPCWID supply depends on the relative positive effect of reducing depletions from pumping compared to the negative effect of turning off Texas WWTP discharges. During 1951-1978, EPCWID diversions increase by an average of 200 AF, but FHG deliveries increase by an average of 2,600 AF. During the mostly full supply years of 1979-2005, EPCWID diversions increase by an average of 10,200 AF to replace the significant reduction in WWTP discharges to the EPCWID canal system.

The reduction in the Texas WWTP discharges due to turning off the non-irrigation pumping and the concurrent increased deliveries of Project water to EPCWID, along with the reduction in stream depletions caused by Texas Mesilla irrigation pumping results in increased Rio Grande at El Paso flow in many years, particularly in the 1980s and 1990s. During 1985-2005, El Paso flows increase by an average of 27,800 AF during the irrigation season, excluding spills.

30.4 MX Pumping Off (Run 5)

In Run 5, all supplemental pumping in JID and all municipal pumping and associated WWTP discharges in Ciudad Juarez is turned off. Turning off pumping in Mexico has much less effect on Project operations than turning off pumping in New Mexico or Texas.

Turning off Mexico pumping reduces the river and conveyance system losses in delivering Project water to EPCWID farmers. As a result, in full supply years, less water needs to be released from storage to meet EPCWID demands. This results in an accumulation of water in storage that increases allocations and deliveries in later non-full supply years. This is seen in the increased reservoir releases and deliveries in 1955, 1964, 1967, 1977, 1978 and several other years after 2000.

EBID FHG deliveries increase by an average of 2,400 AF during 1951-1978, and 2,400 AF during 2006-2017. EPCWID FHG deliveries increase by similar amounts averaging 1,500 AF during 1951-1978 and 2,100 AF during 2006-2017. The impact of Mexico pumping on the HCCRD supply is larger than on EBID or EPCWID, with the total irrigation season supply to HCCRD increasing by an average of 3,900 AF during 1951-2007.

Mexico pumping also has a large impact on ground water storage in the Hueco. From 1951-2017, Hueco ground water storage is depleted by an average of 59,500 AF/y. The effect of Juarez pumping from the new Conejos-Medanos wellfield is evident in the recent changes in Rincon-Mesilla ground water storage.

30.5 R-M Pumping Off (Run 6)

In Run 6, all irrigation pumping and non-irrigation pumping and associated returns in the Rincon and Mesilla basins is turned off. This includes turning off irrigation and non-irrigation pumping in the Texas portion of the Mesilla basin. The purpose of this run is to simulate a scenario that is directly comparable to the 100% reduced pumping run of the Texas Model described in the Hutchison Report.

As expected, the effect of turning off all Rincon-Mesilla pumping in Run 6 has a larger effect than turning off New Mexico pumping in Run 3, but with a similar pattern. Turning off R-M pumping increases the Project delivery efficiency by increasing drain flows, reducing river losses, and reducing canal seepage. In full allocation years, releases from storage can be reduced while still delivering full allocations to EBID and EPCWID. This accumulates water in storage leading to increased allocations and deliveries in dry years, and greater spills in very wet years.

As discussed in Section 18.0, the comparisons of simulated changes in El Paso flow between the ILRG Model and the Texas Model that were presented in the SWE Report were revised with results from the updated ILRG Model. The revised results are shown in revised **Figures 13-1** and **13-2** in **Appendix 18**.

Additional comparisons of the R-M Pumping Off results to comparable runs of the Texas Model presented in the Hutchison Report and the Second Supplemental Moran Report are presented in **Table 30-3**. These include comparisons of 1951-2016 averages for selected model outputs for the updated ILRG Model (Run 6), the Texas Model without reoperation (Hutchison; 100% R-M Pumping Off), and the Texas Model with crude redistribution (Moran; 100% R-M Pumping Off). The updated ILRG Model results are summarized as annual averages and irrigation season averages. The Texas Model results are annual averages consistent with the annual stress periods in the Texas Model. The table entries for the Texas Model shown as "n/a" and shaded grey indicate outputs that are not simulated in the Texas Model.

Table 30-3 highlights many of the processes simulated in the ILRG Model that are not simulated in the Texas Model. It also contrasts long-term average differences between the models as to simulated changes in Rincon-Mesilla diversions and FHG deliveries, and El Paso flows. During 1951-2016, the average annual change in El Paso flow in the Texas Model is 124,700 AF without reoperation (Hutchison) and 51,700 AF with crude redistribution (Moran). These results compare to the change in flow in the ILRG Model that averages 79,800 AF year-around, and 33,200 AF during the irrigation season, excluding spills. The change in flow goes down to 12,900 AF during the irrigation season from 1985-2005.

30.6 TX Mesilla Pumping Off (Run 7)

In Run 7, all supplemental irrigation pumping and non-irrigation pumping in the Texas portion of the Mesilla basin is turned off. This includes turning off the EPW Canutillo wells and associated M&I return flows. The results of this run show that turning off Texas-Mesilla pumping has, on average over the whole study period, more impact on Project operations than does turning off all Texas pumping in Run 4. This is due to significant WWTP offsets that occur in Run 4.

Similar to many of the runs described above, turning off Texas-Mesilla pumping and returns increases the Project delivery efficiency due to increased drain flows, reduced river seepage, and reduced canal seepage. In turn, this reduces reservoir releases needed to deliver full supply allocations in wet years and the resulting storage accumulations increase allocations and deliveries in dry years.

Turning off Texas-Mesilla pumping causes EBID diversions to increase by an average of 7,200 AF during 1951-1978 and 21,300 AF during 2006-2017. EBID FHG deliveries increase in a similar pattern with average increases of 5,800 AF in 1951-1978 and 12,500 AF in 2006-2017. Impacts during recent years are magnified by the effect of the 2008 OA on EBID allocations.

EPCWID operations are also impacted by Texas-Mesilla pumping. Average irrigation season diversions by EPCWID increase by an average of 4,100 AF during 1951-1978 and 2,600 AF during 2006-2017. EPCWID FHG deliveries during 1951-1978 increase by an average of 2,600 AF and during 2006-2017 by an average of 400 AF.

30.7 TX Non-Irrigation Pumping Off (Run 8)

In Run 8, all Texas non-irrigation pumping and associated urban return flows are turned off. This includes pumping by EPW and other minor pumpers from the Hueco and pumping from EPW's Canutillo wellfield in the Mesilla Valley. Discharges from EPW's WWTPs are turned off except for amounts attributed to EPW's use of Project water which continue to be simulated. All urban deep percolation is also similarly eliminated or reduced.

Turning off the non-irrigation pumping and returns in Texas results in EPCWID ordering more Project water to replace the loss in WWTP discharge supply. This reduces the supply available for allocation in some dry years resulting in reduced diversions and/or deliveries to EBID and EPCWID.

EBID diversions decrease by an average of 2,900 AF during 1951-1978. After the 2008 OA becomes effective, the increases in Project water diversions by EPCWID to replace the reduced WWTP discharge supply increases the computed diversion ratio resulting in EBID diversions increasing by an average of 12,100 AF during 2006-2017. EBID FHG deliveries change by corresponding amounts with an average decrease of 1,000 AF from 1951-1978 and an average increase of 7,600 AF from 2006-2017.

Turning off Texas non-irrigation pumping causes EPCWID to order more Project water to replace the lost WWTP returns. There is a modest increase in diversions during 1951-1978 averaging 2,500 AF/y, which is followed by a much larger increase in diversions during 1979-2005 averaging 14,300 AF/y.

30.8 NM Non-Irrigation Pumping Off (Run 9)

In this scenario, all non-irrigation pumping in New Mexico along with the associated WWTP discharges and urban deep percolation are turned off. The effects are similar in pattern, but much smaller than the effects of turning off all New Mexico pumping in Run 3.

The familiar pattern of accumulated water in Project storage in wet years followed by increases in allocation and releases in dry years is repeated in Run 9. EBID diversions increase by averages of 2,500 AF during 1951-1978 and 23,400 AF during 2006-2017 when the effects of pumping are elevated by interaction with the revised allocation procedure under the 2008 OA. EBID FHG deliveries increase proportionally by an average of 2,000 AF/y during 1951-1978 and 14,100 AF/y during 2006-2017.

EPCWID diversions and FHG deliveries increase by small amounts when the non-irrigation pumping in New Mexico is turned off. On average, irrigation season diversions for

EPCWID increase by 900 AF during 1951-1978 and 4,500 AF during 1985-2017. Irrigation season FHG deliveries to EPCWID increase by 800 AF from 1951-1978 and 2,000 AF during 1985-2017.

The increases in Rio Grande at El Paso flow during the irrigation season are generally limited to times of increased deliveries to EPCWID, and these average 4,000 AF during 1951-2017. The increases in El Paso flow during the non-irrigation season and during spills average 2,100 AF during 1951-2017.

30.9 MX Non-Irrigation Pumping Off (Run 10)

In this scenario, all non-irrigation pumping for Ciudad Juarez in Mexico along with the associated sewage/WWTP returns are turned off. Mexico non-irrigation pumping has a relatively minor effect on Project operations and deliveries to EBID and EPCWID. For the analysis of all Mexico groundwater pumping off, refer to Run 5 in section 30.4 above.

Mexico irrigation pumping increases due to loss of Juarez WWTP discharges. This in turn increases EPCWID conveyance losses resulting in EPCWID having to increase diversions to deliver similar amounts to the farms. EPCWID irrigation season diversions increase by an average of 700 AF/y during 1951-2017, and FHG deliveries increase by an average of 200 AF over the same period. The increase in EBID diversions and FHG over 1951-2017 is minimal averaging 300 AF.

30.10 2008 Operating Agreement Scenarios (Runs 11 and 12)

Two runs of the ILRG Model were made to evaluate the effect of the D3+Carryover accounting in the 2008 OA on Project operations and LRG water supplies. In Run 11, the D1/D2 allocation procedure is simulated to allocate Project water during the entire period from 1950 - 2017 period, and in Run 12 the D3+Carryover accounting is simulated during this 68-year period[5]. Otherwise, both runs employ the same RiverWare simulation rules that are used in the Historical Base Run. Irrigation pumping is computed based on the unmet irrigation demand and the non-irrigation pumping and associated return flows are set at historical levels.

Comparison of the results of Run 11 to Run 1 show the effects of the 2008 OA on Project operations in Run 1 compared to what would have happened had the 2008 OA not been implemented and the D1/D2 allocation procedure been left in place.

[5] The RiverWare rules do not simulate annual allocations during the wet period from 1940 – 1949.

When the D1/D2 allocation procedure is left in place during 2006-2017, the annual allocations to EBID increase substantially in most years during this period resulting in large increases in EBID diversions averaging 94,200 AF and in EBID FHG deliveries averaging 54,600 AF. These impacts on EBID from the 2008 OA are far greater than the impacts of New Mexico pumping on EPCWID irrigation season FHG deliveries that average 17,800 AF during 2006-2017 as shown in the Run 3 results.

Conversely EPCWID diversions decline by an average of 23,000 AF and FHG deliveries decline by an average of 17,200 AF during 2006-2007. The reason for the decline in EPCWID supply is primarily due to the limited amount of Project water in storage. The increases in EBID's allocations and deliveries result in smaller amounts of Project water to allocate between the districts in subsequent years. Another factor is the absence of carryover for the individual districts and this results in more water allocated to EBID and less water available for EPCWID to use.

Comparison of the results of Run 12 to Run 11 allows differences between the D1/D2 and D3+Carryover allocation procedures to be evaluated over the entire 1950-2017 period. The differences between these runs are computed based on Run 12 (D3+CO) minus Run 11 (D1/D2) and therefore reflect the impacts of going from the D1/D2 allocation procedure to the D3+CO allocation procedure.

Comparison of Run 12 and Run 11 shows clearly the effect of the 2008 OA on EBID varies depending on the type of year. In wet years with a relatively high diversion ratio, the annual EBID allocation is greater under the D3+CO method than under D1/D2 method and this results in increased diversions and FHG deliveries during 26 of the 67 years between 1951-2017 period (1951-1952, 1959-1962, 1982-2001). EBID diversions and FHG deliveries were lower in the other 41 years which were generally years of average and below average water supply. On average during 1951-2017, EBID diversions declined by 34,400 AF and FHG deliveries declined by 19,800 AF.

Conversely, the 2008 OA has a positive effect on EPCWID allocations, diversions, and FHG deliveries in most years. During the irrigation season, diversions increased by an average of 13,100 AF and FHG deliveries increased by an average of 8,200 AF. The average increase in EPCWID supply is much less that the average decrease in EBID supply.

The following is a summary of the average annual effect on EBID and EPCWID FHG deliveries in dry, wet, and all years during the 1951-2017 period.

Cumulative Volume Impact of 2008 Operating Agreement on March - October FHG Deliveries In Wet and Dry Periods 1951-2017

Condition	Years	EBID	EPCWID
Dry	1953-1958, 1963-1981, 2002-2017	-2.47 MAF	+0.37 MAF
Wet	1951-1952, 1959-1962, 1982-2001	+1.14 MAF	+0.17 MAF
All	1951-2017	-1.33 MAF	+0.55 MAF

The results in the above table show that the 2008 OA takes away critical surface water in the dry years when EBID has a greater need for water (2.47 MAF) than it gives back to EBID in wet years when the need is less (1.14 MAF) As a result, the 2008 OA forces EBID to pump more ground water in dry years to make up for the reduction in surface water supplies. The increased EBID pumping negatively affects the diversion ratio which contributes to the reduction in water allocated and delivered to EBID in dry years. This was termed a "vicious cycle" by Dr. Barroll (2019, 2020a).

30.11 Reduced Waste (Run 13)

As was described in Section 5.0 of the SWE Report, beginning with the 1950s drought and continuing through the 1970s, Reclamation was able to operate the Project with reported operational waste below 10% during most years. In a few years during the wet periods of the mid-1980s and mid-1990s, the EBID waste increased to approximately 20%. The situation in EPCWID was markedly different than in EBID from the 1980s through the 2000s (after EPCWID took over operations) with the operational waste consistently in the range of 20% to 30%.

A run of the ILRG Model was made to evaluate the benefit to the Project from reducing the operational waste. The RiverWare operational rules were modified so that the operational waste was limited to the lesser of the historical amounts or 10% of the simulated diversions.

Limiting operational waste in both Districts to no more than 10 percent reduces releases from Project storage in full allocation years resulting in increased allocations and deliveries in dry years with less than full allocations. As a result of the more efficient Project operation, FHG deliveries to EBID and EPCWID increase in many years during the

1950s – 1970s, and again after 2002. Increases in FHG deliveries to EBID average 35,300 AF during 1951-1978 and 57,300 AF during 2006-2017. Increases in FHG deliveries to EPCWID average 17,800 AF during 1951-1978 and 18,500 AF during 2006-2017.

30.12 Hueco Pumping Off (Runs 14, 14a, 14b, 14c, and 14d)

In response to questions from Texas legal counsel during depositions of the New Mexico experts, and in response to opinions from Texas and U.S. experts, several runs of the ILRG Model were made in which all or a portion of the pumping in the Hueco was turned off, as well as runs in which pumping was turned off without turning off WWTP discharges and vice-versa. The results from these runs are useful in assessing the effects of the Hueco pumping in isolation from pumping in other areas of the LRG basin and the effect of WWTP discharges in offsetting impacts from Hueco pumping.

The No Hueco Pumping Scenarios is simulated in the same manner as the other no pumping scenarios. The supplemental irrigation pumping from the Hueco in Texas and/or Mexico is turned off. In addition, the non-irrigation pumping in these areas and the corresponding WWTP and urban deep percolation return flows are also turned off. Specifications and summaries of the results of the No Hueco Pumping Scenarios are presented below. Runs 14a, 14b, 14c, and 14d were made to test various components of Run 14.

- All Hueco Pumping Off (Run 14) – In Run 14, all supplemental irrigation pumping and non-irrigation pumping in the Hueco in Texas and Mexico is turned off. In addition, the WWTP discharges by EPW and Ciudad Juarez from their Hueco pumping are turned off, as is the urban deep percolation from EPW[6].

  There are opposing effects within EPCWID from turning off Hueco pumping. Turning off Hueco pumping reduces canal and lateral losses in EPCWID and reduces river seepage between American Dam and Riverside Dam before the ACE was constructed in 1999. These changes can result in reduced Project water orders to deliver the same amount of water to EPCWID farm headgates. On the other hand, the reduction in WWTP discharges to the EPCWID canal system when M&I pumping is turned off reduces the irrigation supply available to deliver to EPCWID farm headgates and increases RHG demands for Project water. These opposing effects can result in net increases or decreases in annual EPCWID FHG deliveries.

[6] No urban deep percolation is simulated for Mexico in the historical Base Run.

The effects within EPCWID from turning off Hueco pumping can propagate upstream and impact reservoir operations and deliveries to EBID depending on whether it is a full allocation year or non-full allocation year. In full allocation years, there is little effect on EBID FHG deliveries because EBID's allocation does not change. In non-full allocation years, accumulated changes in reservoir storage resulting from changes in EPCWID orders of Project water can result in changes in EBID allocations and deliveries.

When Hueco pumping is turned off in Run 14, there are some increases and decreases in EBID FHG deliveries that average to a 1,500 AF increase during 1951-2017 with the increases occurring in dry years.

Turning off Hueco pumping increases EPCWID FHG deliveries by an average of 800 AF during 1951-2017. Turning off Hueco pumping results in a substantial increase in the total HCCRD supply (RHG diversions) averaging 7,500 AF during 1951-2017.

- Texas Hueco Pumping Off (Run 14a) – In Run 14a, all supplemental irrigation pumping and non-irrigation pumping by Texas in the El Paso Valley is turned off, along with the WWTP discharges and urban deep percolation from the EPW Hueco pumping.

  Turning off Texas Hueco pumping reduces EBID FHG deliveries by an average of 1,000 AF during 1951-2017. EBID FHG deliveries decrease by an average of 4,000 AF during 2006-2017 when the 2008 OA is in effect.

  During 1985-2017, Texas Hueco pumping reduces EPCWID FHG deliveries during the irrigation season by an average of 1,400 AF and increases the total flow to HCCRD an average of 2,100 AF.

  Contrary to the claims of the Texas and U.S. experts, the impacts of Texas Hueco pumping on Project operations and surface water supplies to EBID, EPCWID, and HCCRD are not negligible.

- Mexico Hueco Pumping Off (Run 14b) – In Run 14b, all supplemental irrigation pumping and non-irrigation pumping in the Mexico portion of the Hueco is turned off, along with the WWTP discharges from Ciudad Juarez pumping.

  Turning off Mexico pumping reduces canal seepage and river seepage in EPCWID causing reduced Project orders at EPCWID canal headings. This results in accumulation of water in Project storage that increases Project water deliveries to EBID in years with less than a full Project water allocation. Simulated increases in

EBID FHG deliveries average 1,700 AF during 1951-2017, and 3,200 AF during 2006-2017, with increases exceeding 5,000 AF in several years and 10,000 AF in 2010.

Turning off Mexico Hueco pumping has similar effects on EPCWID with FHG deliveries increasing by an average of 1,500 AF during 1951-2017. The increase in total HCCRD supply is greater averaging 3,900 AF during 1951-2017.

- <u>Texas WWTP Discharges Off (Run 14c)</u> – In Run 14c, all discharges from Texas WWTPs are turned off. This includes turning off discharges from the EPW's Northwest, Haskell, Socorro, and Bustamante WWTPs, as well as discharges from the Anthony TX WWTP and the Fabens WWTP. The purpose of this run is to quantify the benefit to the Project operations and LRG water users from the Texas WWTP discharges. Without these discharges, the impacts of Texas Hueco pumping would be much larger.

  When the Texas WWTP returns are turned off, EBID FHG deliveries decrease markedly in numerous years with less than full allocations. This shows the interconnected nature of the Project and how changes in supply at the bottom of the Project area can ripple through the Project and affect operations hundreds of miles upstream. On average during 1951-2017 the reduction in diversions averages 14,600 AF and the reduction in FHG deliveries averages 6,600 AF.

  Turning off Texas WWTP discharges results in increased Project releases and diversions to EPCWID to replace the reduction in irrigation supply to EPCWID farmers from the WWTP discharges. This results in large increases in El Paso flows to deliver additional Project water to EPCWID, particularly during the wet period in the 1980s and 1990s. The increase in El Paso flows during the irrigation season, excluding spills, average 38,300 AF during 1985-2005.

  Without the Texas WWTP discharges, the simulated impacts from Texas pumping would be much larger than the impacts shown in Runs 4, 7, 8, 14, and 14a. The results for Run 14c show the effect of Texas WWTP discharges have in offsetting the impacts of Texas pumping. Without these discharges (for example if EPW reused its WWTP discharges for non-potable uses), the effects of Texas pumping on Project operations, including deliveries to EBID would be much greater.

- <u>Texas Hueco Pumping Off without WWTP Discharges Off (Run 14d)</u> – In Run 14d, Texas Hueco pumping is turned off without turning off the associated Texas WWTP discharges and urban deep percolation. This test run simulates the effect of Texas Hueco pumping without the offsets from Texas M&I return flows.

When the Texas Hueco pumping is turned off without turning off the M&I returns, the simulated impacts on Project operations increase. EBID FHG deliveries increase by an average of 5,000 AF during 1951-1978 and 2,000 AF during 2006-2017. FHG deliveries to EPCWID increase by 4,600 AF during 1951-1978 and 2,000 AF during 2006-2017. Total flows to HCCRD increase by 7,100 AF during 1951-1978 and 3,700 AF during 2006-2017.

30.13 Early EPCWID Ops (Runs 15, 15a, 15b, 15c)

Four scenarios were simulated using the ILRG Model to evaluate the effects on Project operations that would result from a return to EPCWID operations consistent with how the Project was operated in the past. These include simulating increased irrigation use of drain flows in the Fabens area and charging EPCWID for all water that it uses. Runs 15a, 15b, and 15c were made to test various components of Run 15. Descriptions of the four Early EPCWID Ops scenarios are provided below along with the scenario results.

- <u>Early EPCWID Ops (WWTP & Fabens Drains) (Run 15)</u> – In Run 15, simulation of EPCWID operations in the El Paso Valley are modified to simulate irrigation use of all available supplies consistent with how the Project was originally operated in the El Paso Valley. This includes simulation of irrigation use of the usable Fabens drain flows, which are estimated as 70% of the total Fabens drain flows limited to a monthly volume of 6,000 AF, based on available historical data (see response to Ferguson Opinion 9 for more information). In addition, EPCWID is charged for all use of drain flows and WWTP flows, and the ACE Credit and Haskell WWTP discharge credits are disabled. These changes reflect operations consistent with the original concept and implementation of the Project which was to use all available supplies to minimize the amount of storage releases needed to meet Project water demands. Further, since EPCWID is charged for all of its water use including the water that arises within the EPCWID system, it has less unused allocation in many years and uses its entire allocation in more years than in the Historical Base Run (Run 1). The increased use of water arising within the EPCWID system reduces the releases from Project storage to meet EPCWID demands and the accumulated Project storage increases the supply available for allocation and use in subsequent years. When accounting under 2008 OA commences, EPCWID has less unused allocation to carryover to subsequent years. The following is a summary of the effects of the foregoing changes in EPCWID operations:
    - <u>EBID</u> – FHG deliveries increase modestly by an average of 4,300 AF during 1951-1978 and by a much larger amount, averaging 41,900 AF during 2006-2017. The large increases during the recent period result from significant increases in the diversion ratio that result from EPCWID being

charged for all water that it uses, and the positive feedback of increases in the diversion ratio on EBID allocations under D3 accounting.

  - EPCWID – FHG deliveries increase by an average of 1,400 AF during 1951-2017. Simulated EPCWID RHG diversions decrease by an average of 15,100 AF during 1951-2017 as diversions of Project water from the river are eschewed in favor of the supplies arising within EPCWID.

  - HCCRD – The changes in EPCWID operations result in minor reductions in the water flowing to HCCRD. Annual total flow to HCCRD decreases by an average of 3,100 AF during 1951-2017.

- Early EPCWID Ops (WWTP) (Run 15a) – In Run 15a, EPCWID is charged for irrigation use of WWTP flows, and the ACE Credit and Haskell WWTP discharge credits are disabled. However, the simulated use of drain flows is left at the historical levels simulated in Run 1, and EPCWID is not charged for the historical use of the drain flows. The results are similar in pattern to the Run 15 results but smaller in magnitude as follows:

  - EBID – FHG deliveries increase modestly by an average of only 200 AF during 1951-1978, but by much larger amounts averaging 27,200 AF during 2006-2017. Similar to Run 15, the large increases during the recent period result from the effect of an increase in the diversion ratio on EBID allocations under the 2008 OA.

  - EPCWID – FHG deliveries decrease by an average of 1,900 AF during 1951-2017. Simulated EPCWID RHG diversions decrease by an average of 2,900 AF during 1951-2017 with the increased use and charge for supplies arising within EPCWID.

  - HCCRD – Charging EPCWID for use of WWTP flows and elimination of credits against charges reduces the total flow to HCCRD by an average of 500 AF during 1979-2005 and 2,200 AF during 2006-2017

- Early EPCWID Ops (Fabens Drains) (Run 15b) – In Run 15b, the model simulates and charges EPCWID for use of the usable Fabens drain flows as described above in Run 15. However, EPCWID is not charged for use of WWTP flows and is credited for Haskell WWTP discharges and the ACE Credit. The results are similar in pattern to the Run 15 results as follows:

- EBID – FHG deliveries increase modestly by an average of 4,300 AF during 1951-1978, and by an average of 21,800 AF during 2006-2017. Similar to Run 15, the large increases during the recent period result from the effect of an increase in the diversion ratio on EBID allocations under the 2008 OA.

- EPCWID – FHG deliveries increase by an average of 3,100 AF during 1951-2017. Simulated EPCWID RHG diversions decrease by an average of 12,900 AF during 1951-2017 with the simulated increased use and charge for drain flows arising within EPCWID.

- HCCRD – The increased use of drain flows in EPCWID results in a reduction in the total flow to HCCRD averaging 2,600 AF.

- Early EPCWID Ops (TX Hueco Pumping Off) (Run 15c) – In this scenario, the changes to EPCWID operations and accounting from Run 15 were simulated with the Texas Hueco pumping turned off. The effects of Texas Hueco pumping with the modified EPCWID operation were assessed by comparing the results of Run 15c and Run 15. The effects of the Texas Hueco pumping on EBID are mixed due to the opposing effects on EPCWID from pumping and WWTP discharges from pumping.

30.14 Conj Use 1: Hist All Acres D1/D2 (Runs 16 and 16a)

Two scenarios are simulated to evaluate conjunctive use of surface water and ground water within the Rio Grande Project under the D1/D2 allocation procedure with the historical irrigated area that evolved over time (including irrigation of the primary ground water only acres in New Mexico), and with the early EPCWID operations that are simulated in Run 15. In both scenarios, irrigation pumping in EBID and EPCWID is limited based on the irrigation pumping that existed during the 1951-1978 D1/D2 data period. This is implemented by not allowing the 10-year running average pumping after 1978 to exceed the 1951-1978 historical average annual pumping.

- Conj Use 1: Hist All Acres D1/D2 (Hist M&I) (Run 16) – Run 16 essentially combines the early EPCWID operations from Run 15 with the Run 11 continuation of D1/D2 allocation of Project water after 2005 along with a limit on irrigation pumping after 1978. In Run 16, the M&I pumping and returns are set at the historical amounts simulated in Run 1. The results for Run 16 are very similar to Run 15 until 2005. After that time, the differences from Run 1 represent the combination of the early EPCWID operations and continuation of D1/D2 accounting. The following are summaries of the differences between Run 16 and Run 1 after 2005:

  - EBID – FHG deliveries increase by an average 69,000 AF during 2006 -2017 which is much greater than the increase of 41,900 AF in Run 15.
  - EPCWID – FHG deliveries decrease by an average of 14,500 AF during 2006 -2017 with the D1/D2 accounting compared to an average increase of 700 AF in Run 15.
  - HCCRD – Total flows to HCCRD decline by an average of 9,500 AF during 2006-2017, compared to an average decline of 3,800 AF during this same period in Run 15.

- Conj Use 1: Hist All Acres D1/D2 (1978 M&I) (Run 16a) – The conditions simulated in Run 16a are the same as Run 16 except that M&I pumping in New Mexico and Texas after 1978 is limited to the levels that existed in 1978 at the end of the D1/D2 period. This limit has minimal effect on Texas M&I pumping because it exceeded the 1978 amount by only small amounts in a few years after 1978. When the M&I pumping is limited by the 1978 amount, the simulated M&I returns are scaled down proportionally. The results of Run 16a are very similar to Run 16 which reinforces that New Mexico M&I pumping has relatively little impact on Project operations.
  - EBID – FHG deliveries increase by an average of 72,400 AF during 2006-2017 compared to an average increase of 69,000 AF in Run 16.
  - EPCWID – FHG deliveries decrease by an average of 12,600 AF during 2006-2017 compared to a decrease of 14,500 AF in Run 16.
  - HCCRD – Total supply to HCCRD from 2006-2017 decreases by 9,200 AF compared to an average decrease of 9,500 AF in Run 16.

30.15 Conj Use 2: Hist Proj Acres (Runs 17 and 17a)

A second set of conjunctive use scenarios are simulated in Run 17 and Runs 17a under the D1/D2 allocation procedure with irrigation limited to the historical Project acres and no irrigation of the non-Project primary (ground water only) acres in New Mexico. The early EPCWID operations from Run 15 are also a part of these conjunctive use scenarios.

- Conj Use 2: Hist Proj Acres (Hist M&I) (Run 17) – In Run 17, the M&I pumping and returns are set at the historical amounts simulated in Run 1. The results from Run 17 are similar to the results from Run 16 and the differences largely reflect the effect of ground water pumping on primary acres in New Mexico.

- EBID – Annual FHG deliveries increase by an average of 7,500 AF during 1951-1978, and by a much larger average of 75,600 AF following the change to D1/D2 after 2005.

- EPCWID – Annual FHG deliveries increase by an average 5,100 AF during 1951-1978, and decline by 10,700 AF during 2006-2017 due to the change in allocation method from D3 to D1/D2 starting in 2006.

- HCCRD – Total flows to HCCRD decrease by an average of 8,600 AF during 2006-2017.

- Conj Use 2: Hist Proj Acres (Pre-Comp M&I) (Run 17a) – The conditions simulated in Run 17a are the same as Run 17 except that M&I pumping in New Mexico and Texas is set at the pre-Compact amounts that existed in 1938 (736 AF/y in New Mexico and 13,744 AF/y in Texas). M&I returns are scaled down proportionally consistent with the pre-Compact pumping volumes. The differences between Run 17 and Run 17a reflect the effects of the post-compact increases in total M&I pumping throughout the study area on simulated surface water supplies.

  - EBID – Annual FHG deliveries increase by an average of 9,500 AF from 1951 – 1978 and 87,900 AF from 2006-2017. These compare to an increase of 7,500 AF and an increase of 75,600 AF in Run 17, respectively.

  - EPCWID – Annual FHG deliveries increase by an average 6,100 AF during 1951-1978, and decrease by 4,300 AF during 2006-2017 due to the change in allocation method to D1/D2. These compare to a 1951-1978 increase of 5,100 AF and 2006-2017 decrease of 10,700 AF in Run 17.

  - HCCRD – Total supply to HCCRD increases by an average of 1,100 AF during 1951-2017 compared to an average decrease of 2,800 AF in Run 17.

30.16 Conj Use 3: Auth Proj Acres (Pre-Comp M&I) (Run 18)

A third conjunctive use scenario is simulated in Run 18 under the D1/D2 allocation procedure with irrigation of the original authorized Project acres simulated in every year from 1940-2017 (88,000 acres in EBID and 67,000 acres in EPCWID). The irrigated area in HCCRD is set at the reported maximum historical amount of 17,750 acres that occurred in 1951, and the irrigated area in JID is set at historical levels. M&I pumping and returns are limited to the pre-Compact amounts as in Run 17a. The early EPCWID operations are also simulated as in the other conjunctive use scenarios. Finally, because the authorized EPCWID acres are simulated as irrigated in every year, there is no simulation of EPW use of Project water.

- EBID – Annual FHG deliveries decrease by an average of 1,800 AF during 1951-1978, and increase by 51,500 AF during 2006-2017 under D1/D2.
- EPCWID – Annual FHG deliveries increase by an average of 5,600 AF during 1951-1978 and decrease by an average of 35,700 AF during 2006-2017 when allocations revert back to the D1/D2 method.
- HCCRD – Total supply to HCCRD increases by 500 AF during 1951-1978 and decreases by an average of 13,500 AF during 2006-2017.

31.0 SENSITIVITY ANALYSES OF ILRG MODEL

Alternative runs of the ILRG Model were made to test the sensitivity of the results to changes in certain input parameters and input data. Since ILRG Model results are assessed primarily based on differences between runs, the results of the sensitivity runs were also tabulated based on run differences. The No New Mexico Pumping scenario (Run 3) was selected for the sensitivity analysis, along with the differences in model output compared to the Historical Base Run scenario (Run 1).

The following inputs were selected for sensitivity analysis based on discussions among the New Mexico experts:

- Alluvial Aquifer Hydraulic Conductivity
- River Bed Conductance
- Canal Bed Conductance
- Drain Bed Conductance
- Crop Irrigation Requirement (CIR)

Each of the above inputs was separately perturbated by +10% for the sensitivity runs. Since each of the above inputs are represented in the model as spatially varying values, the 10% perturbation involved applying a scaler of 1.1 to each spatially distributed value. Then, fully iterated runs of the ILRG Model were made to closure for Run 3 and Run 1 (identified as Run 3* and Run 1* in the results summaries). The model inputs being tested were perturbated by 10% in both the RiverWare Model and the two ground water models, except for the CIR which is not an input to the ground water models and canal bed conductance which is perturbed only in the ground water models since canal loss is computed in the ground water models and passed to the RiverWare Model.

The model outputs tabulated and compared for the sensitivity analyses are the same outputs that are summarized in the run comparisons for the alternative model runs described in Section 30.0. The differences in outputs between Run 3* and Run 1* are compared to the differences between the original Run 3 and Run 1, and these comparisons are tabulated in several figures and tables for each input that was tested.

Graphs illustrating the sensitivity analysis results are provided in the bar charts in **Figure 31-1** through **Figure 31-5**. The black bars represent the average Run 3 minus Run 1 differences for the original ILRG Model Runs. As described in more detail in Section 30.0

turning off New Mexico pumping generally results in increased Project storage, decreased Caballo releases, increased diversions and FHG deliveries to EBID, EPCWID, and HCCRD, increased Rio Grande flows at El Paso and Fort Quitman, and increased ground water storage. The orange bars depict the average Run 3* minus Run 1* differences for the sensitivity runs of the ILRG Model. Differences between the black and orange bars reflect the sensitivity of the model outputs to the 10% perturbations of the specified inputs. These differences are summarized as average volumes and average percent changes in **Table 31-1** for each of the five inputs that were tested. The sensitivities of each input are summarized below.

- Alluvial Aquifer Hydraulic Conductivity – Increasing the alluvial aquifer hydraulic conductivity by 10% causes relatively small changes in diversions, FHG deliveries, river flows, and storage (4% or less). These changes generally reflect slight speeding of the surface flow responses to pumping and recharge.

- River Bed Conductance – Increasing the river bed conductance by 10% increases the river gain and loss responses to changes in aquifer heads in hydraulically connected reaches. This in turn slightly increases the surface water response to the cessation of New Mexico pumping in Run 3. More of the pumping effects are expressed as changes in surface water flows and less to changes in ground water storage.

- Canal Bed Conductance – Increasing the canal bed conductance by 10% increases the canal seepage response to changes in pumping and recharge. As a result, turning off pumping in New Mexico results in a modest increase in the effects on diversions and FHG deliveries of the districts (0% - 7%). There are also positive changes in the increases in reservoir and ground water storage (3% - 5%) as well as the increases in river flows from turning off New Mexico pumping (3% - 6%).

- Drain Bed Conductance – Increasing the drain bed conductance by 10% has little effect on the model outputs. The effect on the changes in diversions is only 2% or less, and the effect on reservoir and ground water storage changes is less than 1%.

- Crop Irrigation Requirement (CIR) – Increasing the CIR by 10% has a greater effect on model outputs than any of the other inputs that were tested. This is not surprising because an increase in the CIR has a greater effect on the water budget. Increasing the CIR results in an increase in the unmet demand after the surface water deliveries which in turn increases the simulated pumping in Run 1*. Therefore, when New Mexico pumping is turned off in Run 3*, there are larger computed impacts of pumping on surface water flows than in the base runs. The effect of pumping on diversions and FHG deliveries by the U.S. districts increases by 15% - 43%. The effects of pumping on reservoir storage, river flows, and ground water storage are also significantly affected.

The results of the sensitivity analyses demonstrate that the ILRG Model is most sensitive to changes in CIR because of its substantial effect on the water budget and the unmet irrigation demand that is satisfied by pumping. The other tested parameters mainly affect the timing of ground water flow and the interaction of ground water and surface water interaction as opposed to directly affecting the water budget.

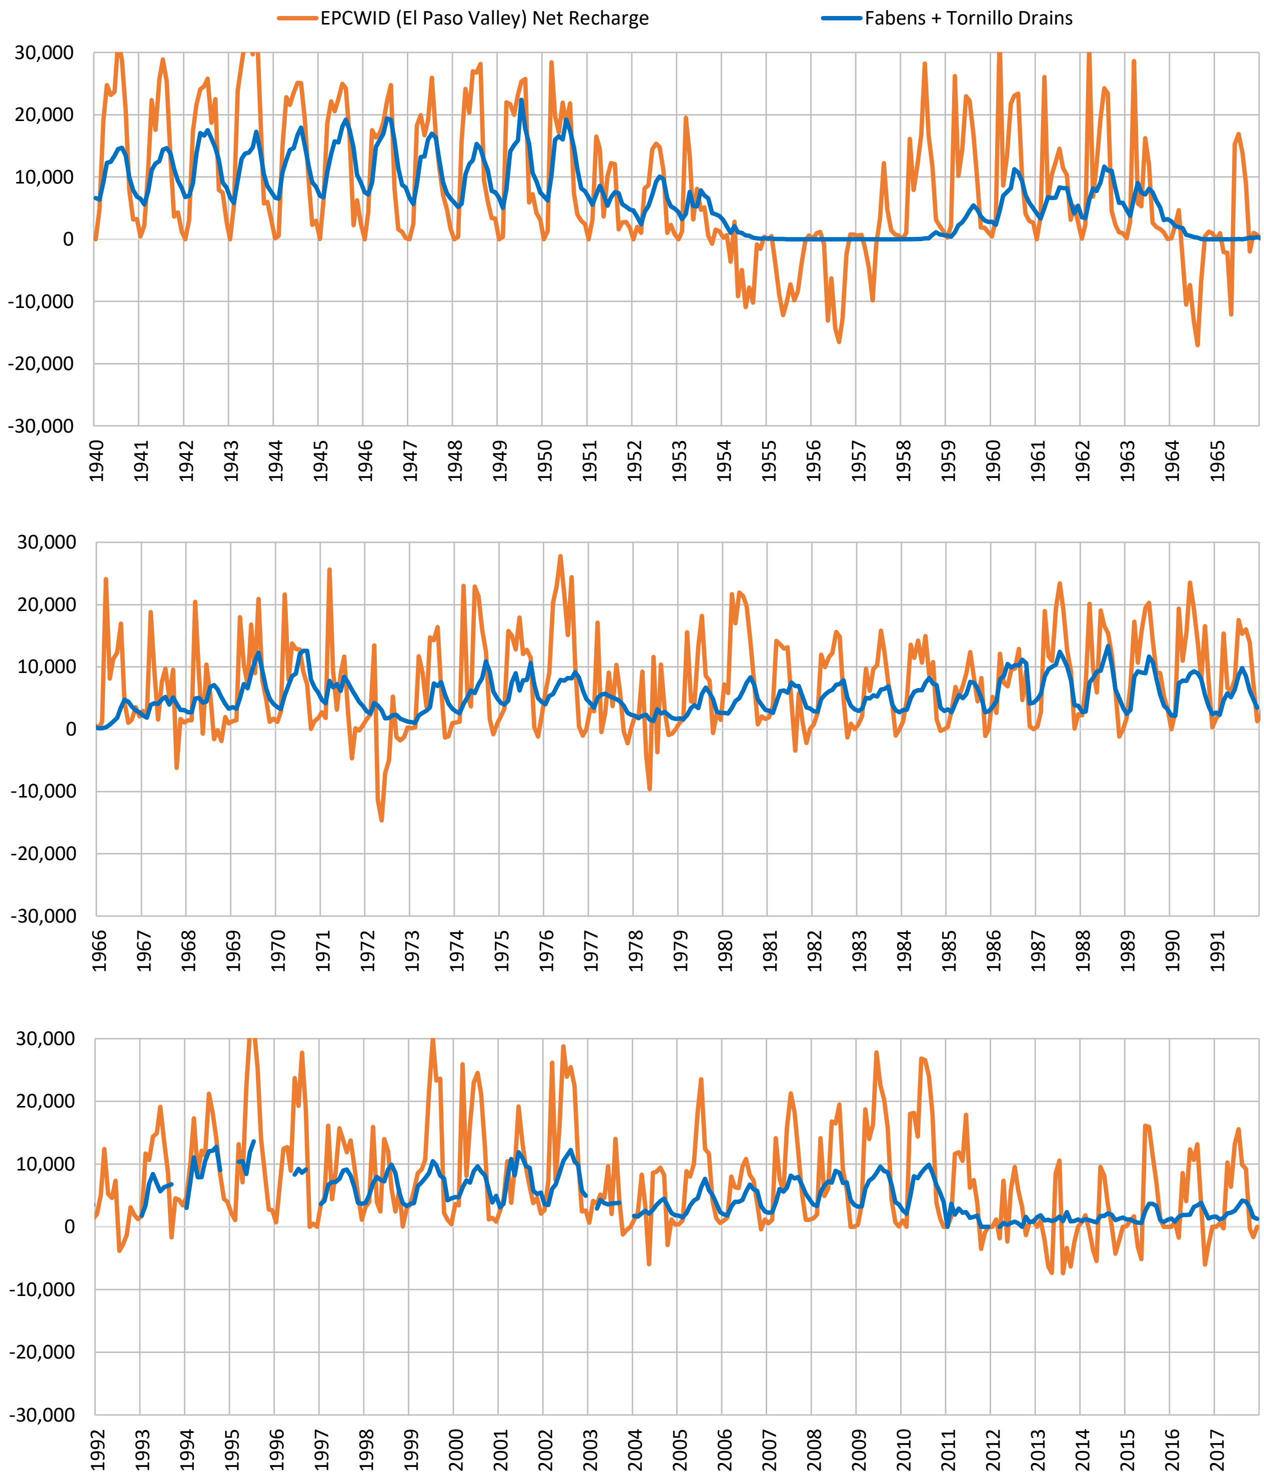
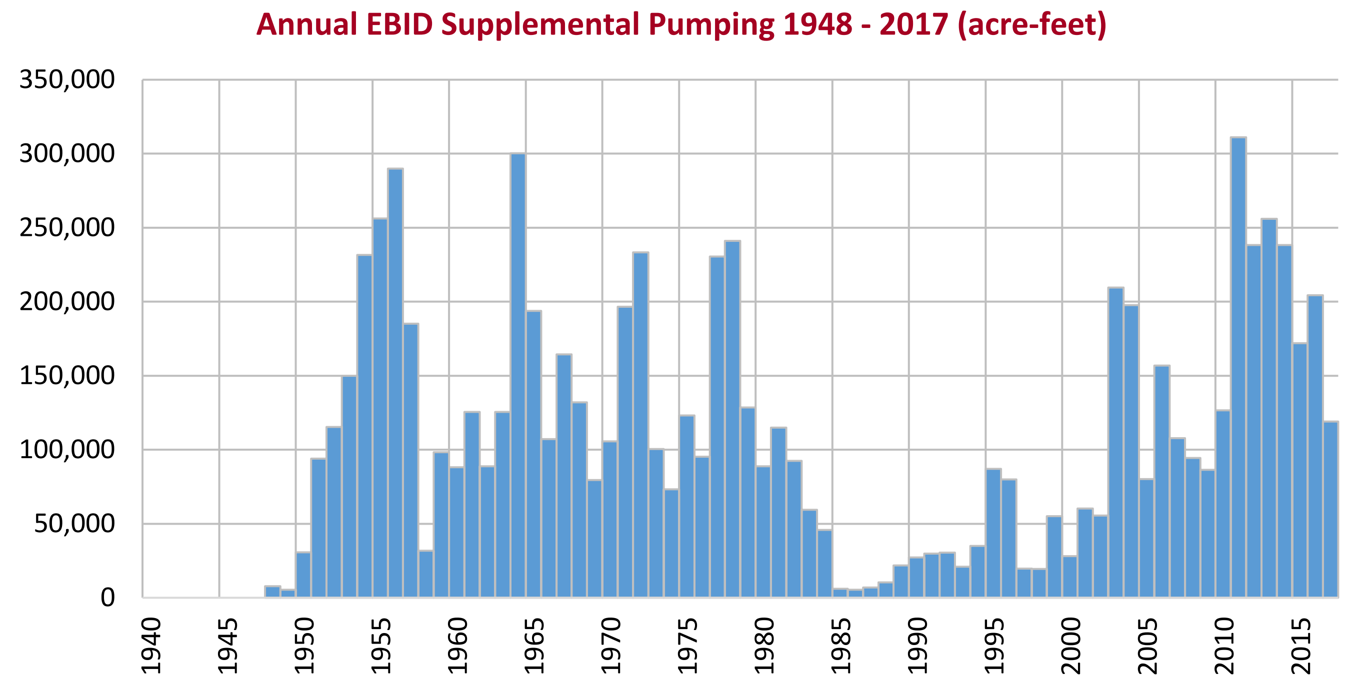
1940 - 2017 (acre-feet)

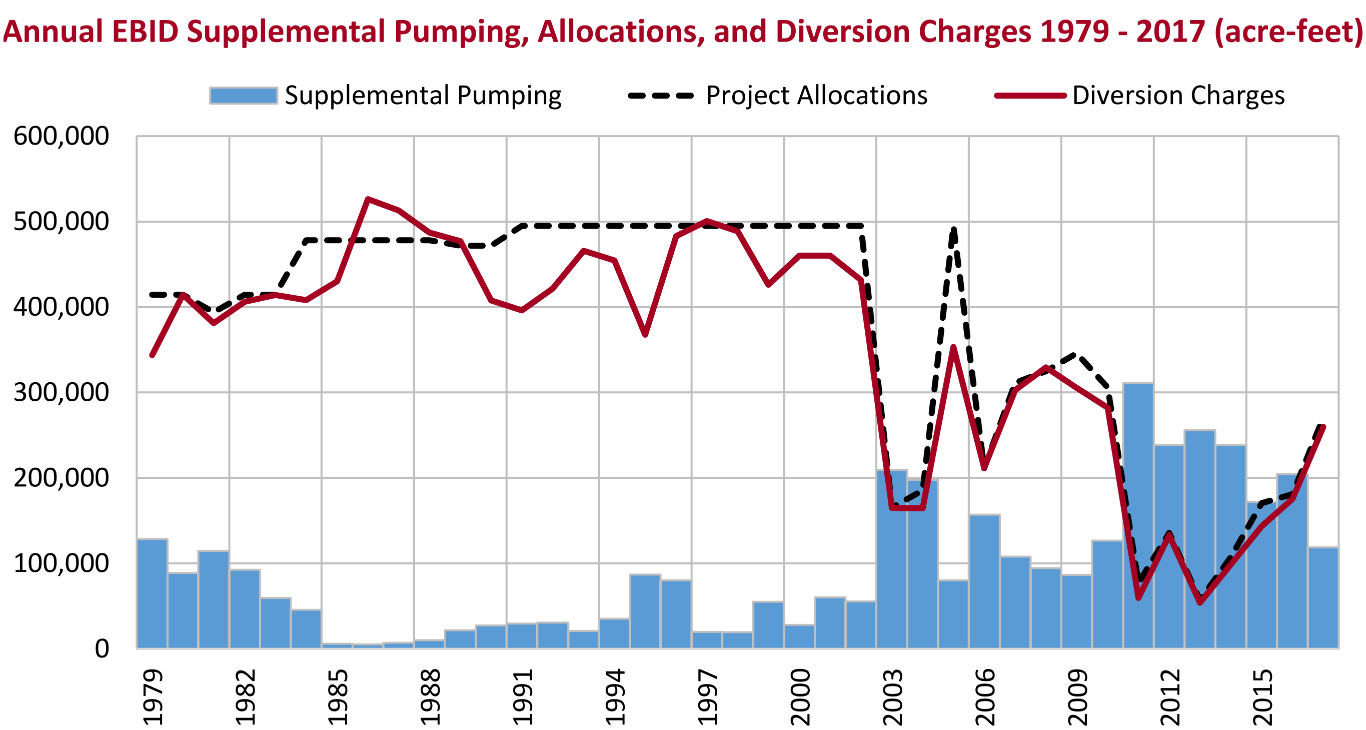


Notes: Net recharge computed as canal seepage plus on farm deep percolation minus pumping from the CFB Model.
Drain flows from SWE SWDataSet. Computed as Tornillo Drain plus Fabens Waste Drain. Fabens Waste Drain flows estimated 1940-1983 as sum of River, Middle, Cuadrilla, Mesa, and Fabens Intercepting drains. Missing Fabens Intercepting Drain flows 1972 - 1983. Missing Fabens Waste Drain flows in 1992, and in certain months in 1993-1996, 2003, and 2012.

Figure 19-4

EBID Pumping, Allocations, and Charges

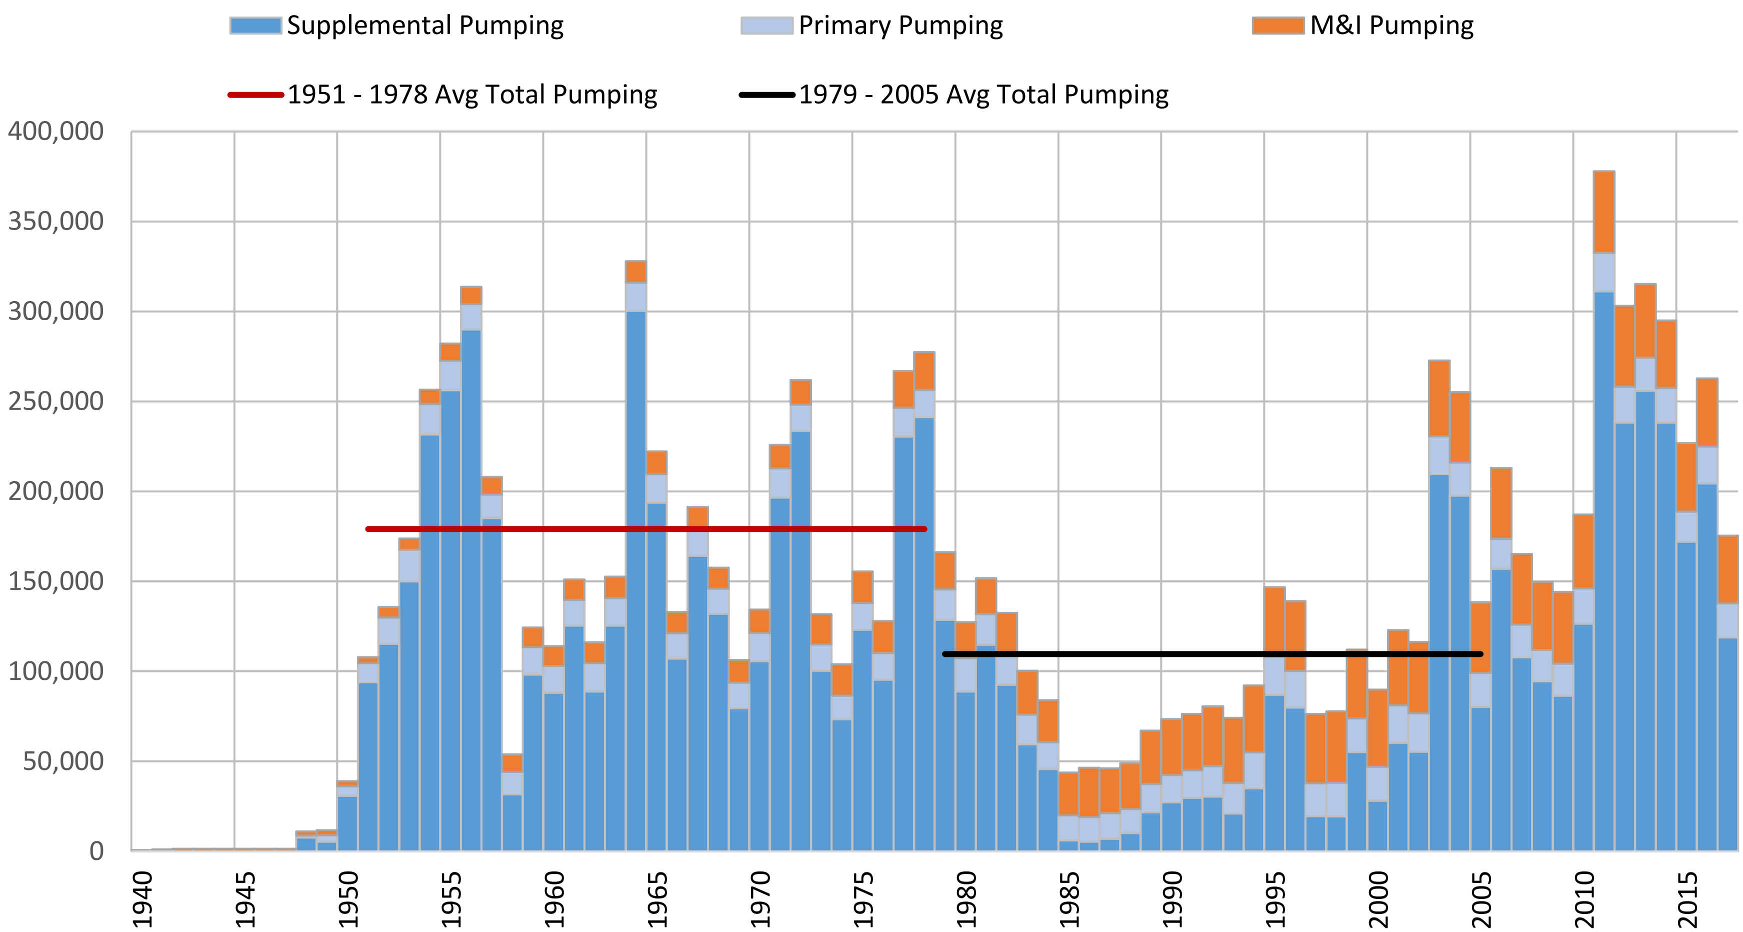




Notes:
(1) Supplemental irrigation pumping from SWE CFB Model.
(2) Annual allocations and diversion charges from SWE Accounting DataSet.

Figure 19-5

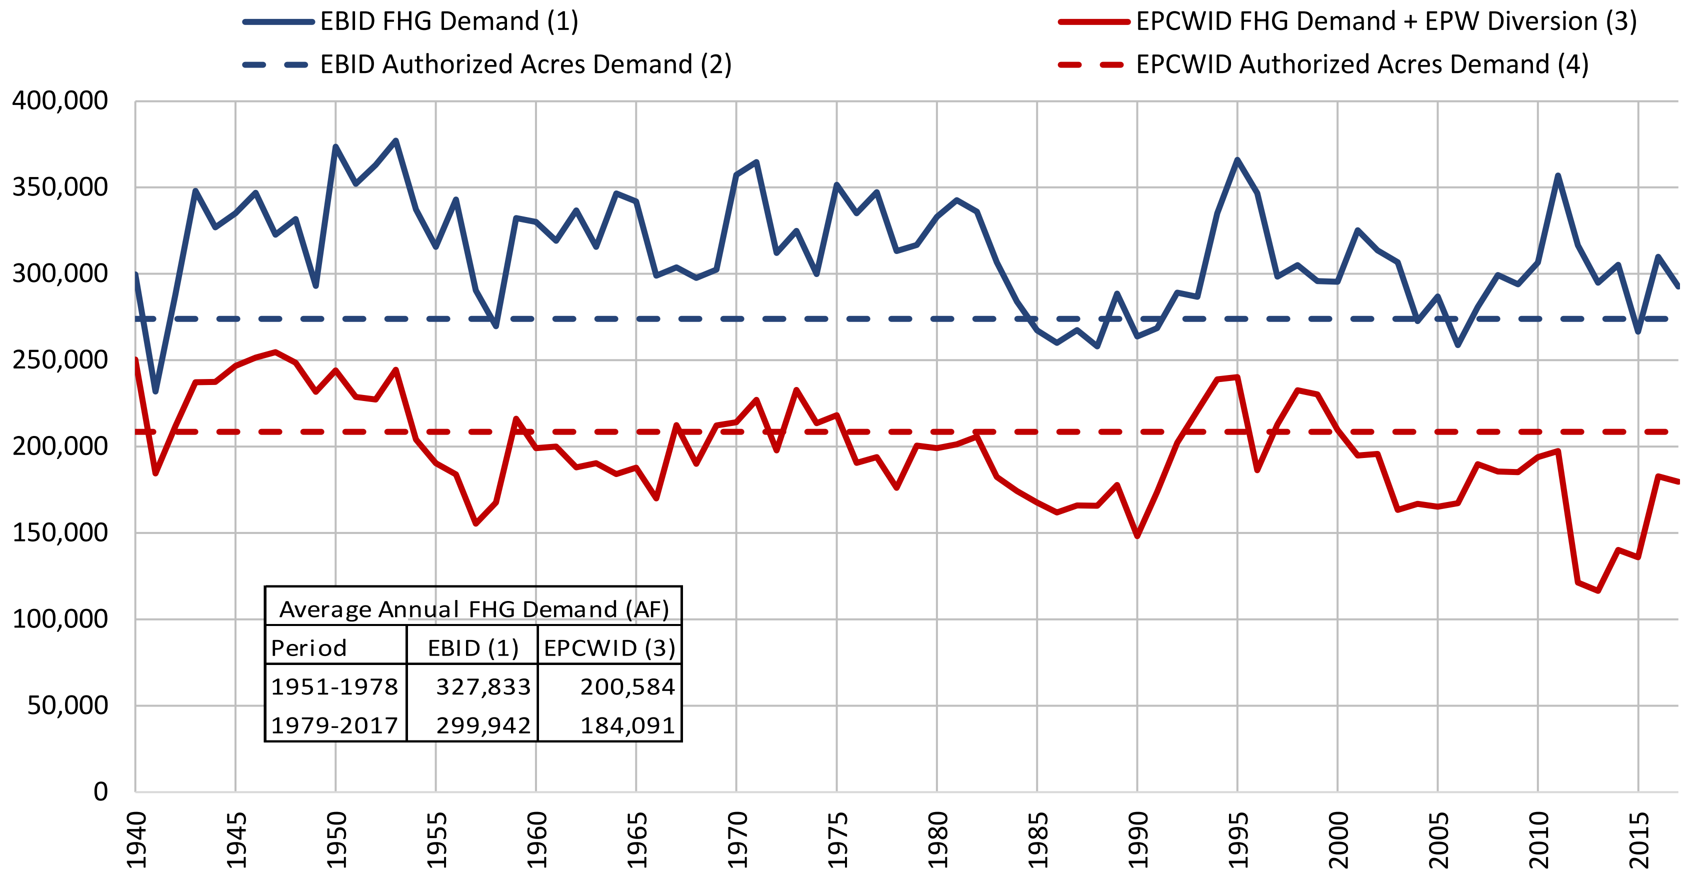
New Mexico Annual Pumping in the Rincon and Mesilla Valleys
1940 - 2017 (acre-feet)



Notes:
(1) New Mexico irrigation pumping from SWE CFB Model.
(2) New Mexico M&I pumping from the NMR-M Model.

Figure 19-6

EBID and EPCWID Annual Farm Headgate Demand
1940 - 2017 (acre-feet)



Average Annual FHG Demand (AF)		
Period	EBID (1)	EPCWID (3)
1951-1978	327,833	200,584
1979-2017	299,942	184,091

Notes:

(1) EBID FHG Demand from SWE CFB Model and computed as weighted supplemental CIR (feet) x irrigated acres /on-farm irrigation efficiency.

(2) EBID Authorized Acres Demand computed as 3.024 AF/acre x EBID authorized acres (90,640).

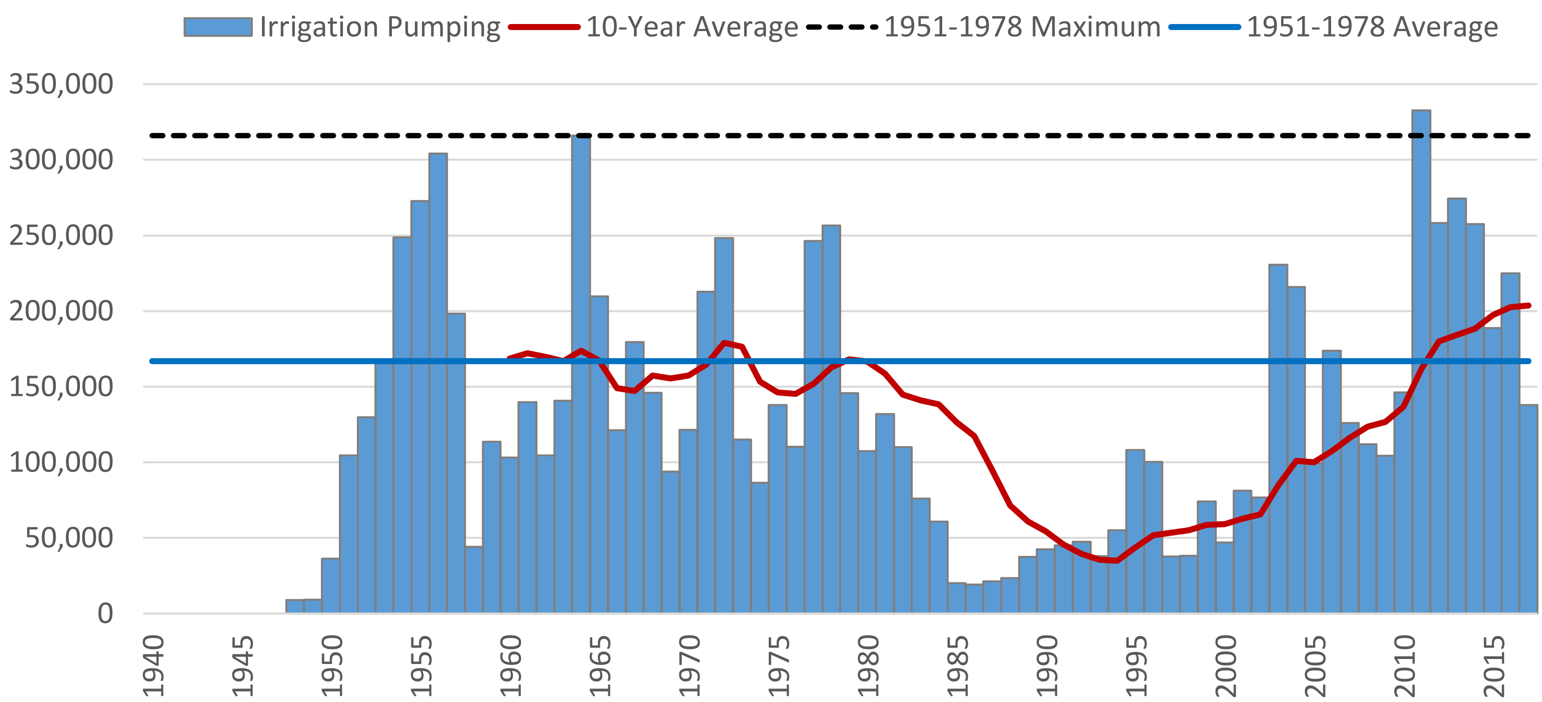
(3) EPCWID FHG Demand from SWE CFB Model and computed as weighted CIR (feet) x irrigated acres /on-farm irrigation efficiency.
EPW Diversion from SWE SWDataSet.

(4) EPCWID Authorized Acres Demand computed as 3.024 AF/acre x EPCWID authorized acres (69,010).

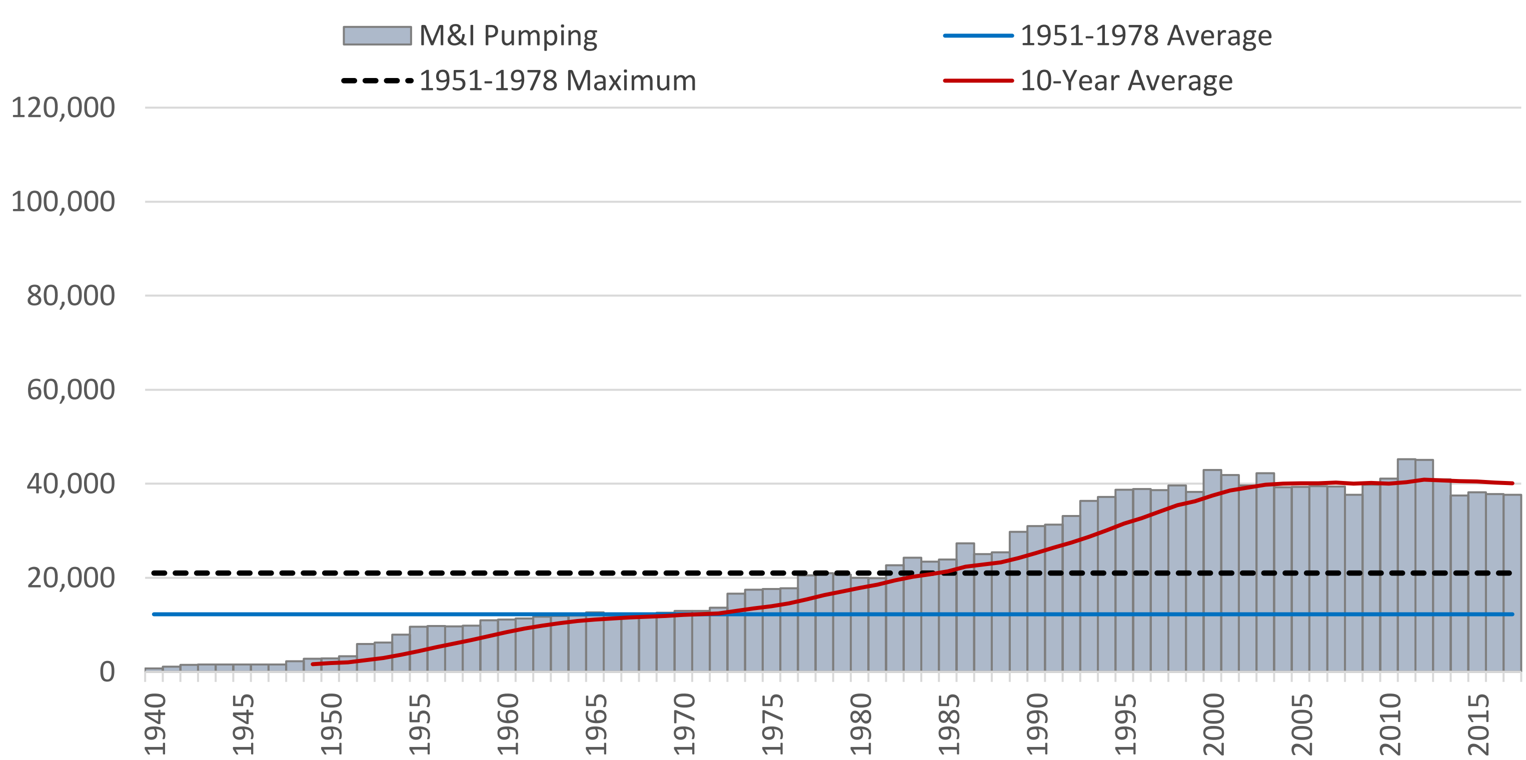
Figure 19-7

Annual New Mexico Pumping
1940 - 2017 (acre-feet)

New Mexico Irrigation Pumping



New Mexico M&I Pumping



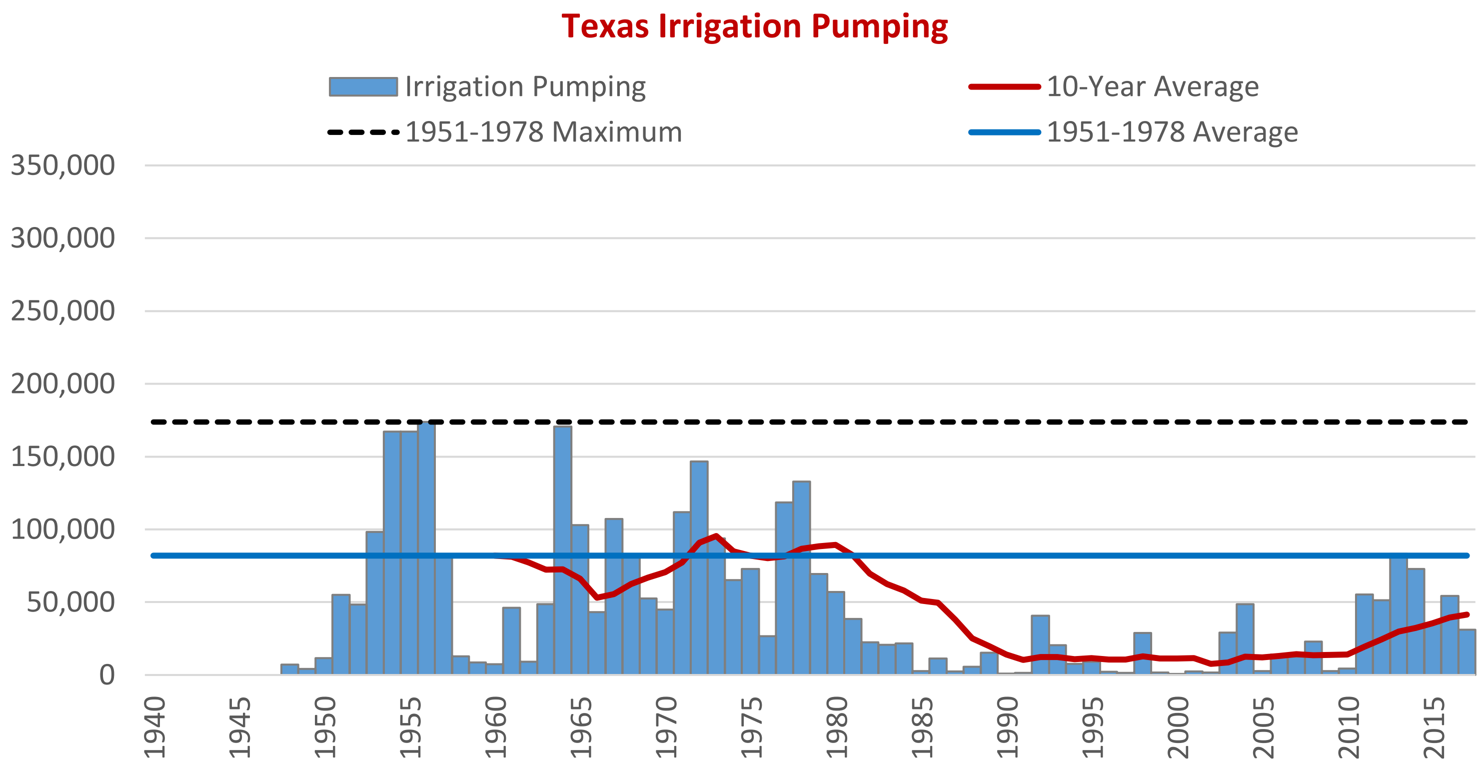
Notes:

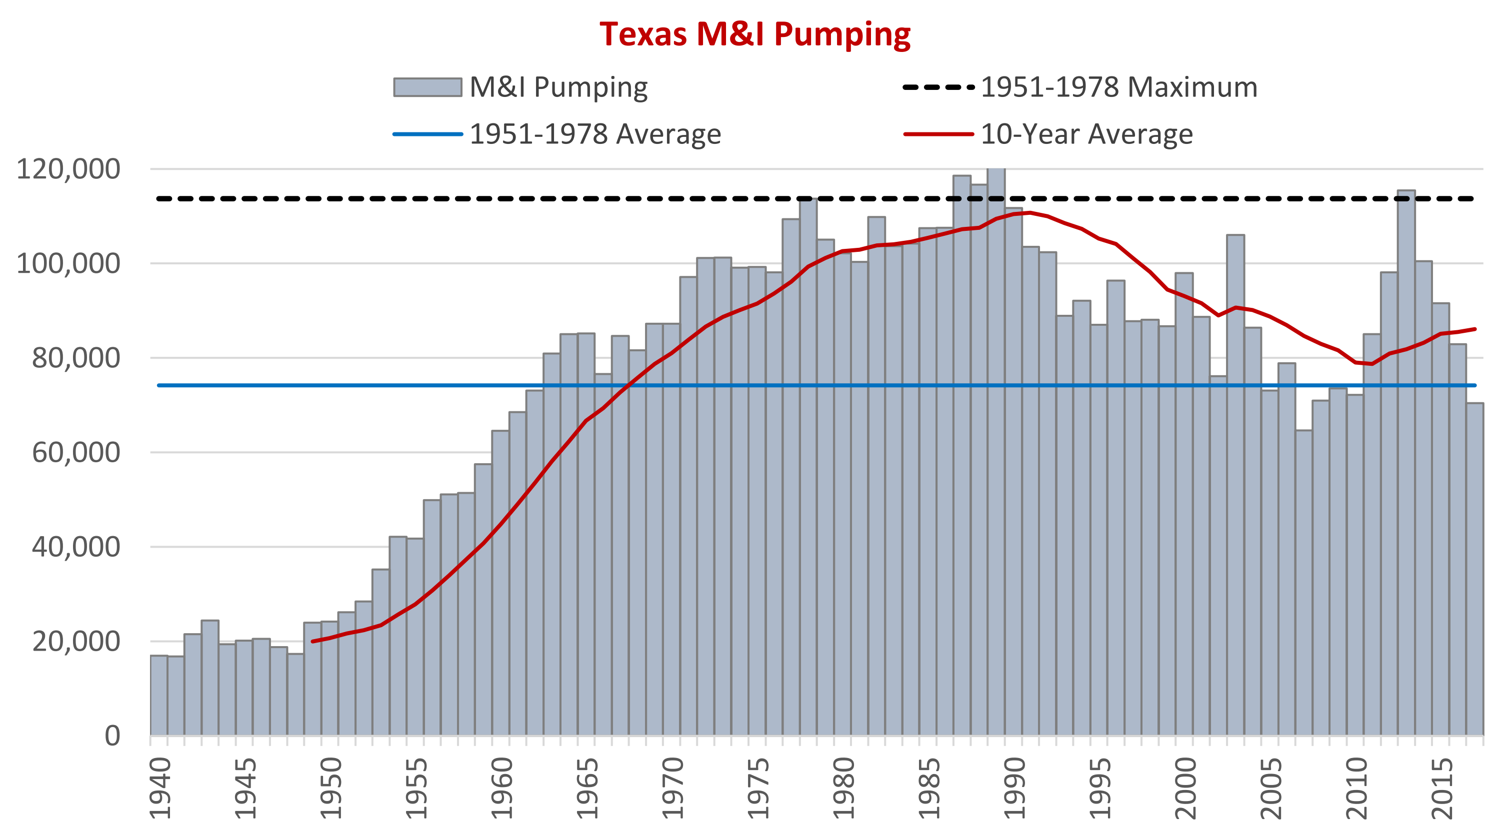
(1) New Mexico irrigation pumping includes EBID supplemental and primary pumping from SWE CFB Model.

(2) New Mexico M&I pumping from NMR-M Model.

Figure 19-8

Annual Texas Pumping
1940 - 2017 (acre-feet)





Notes:

(1) Texas irrigation pumping includes EPCWID and HCCRD pumping from SWE CFB Model.

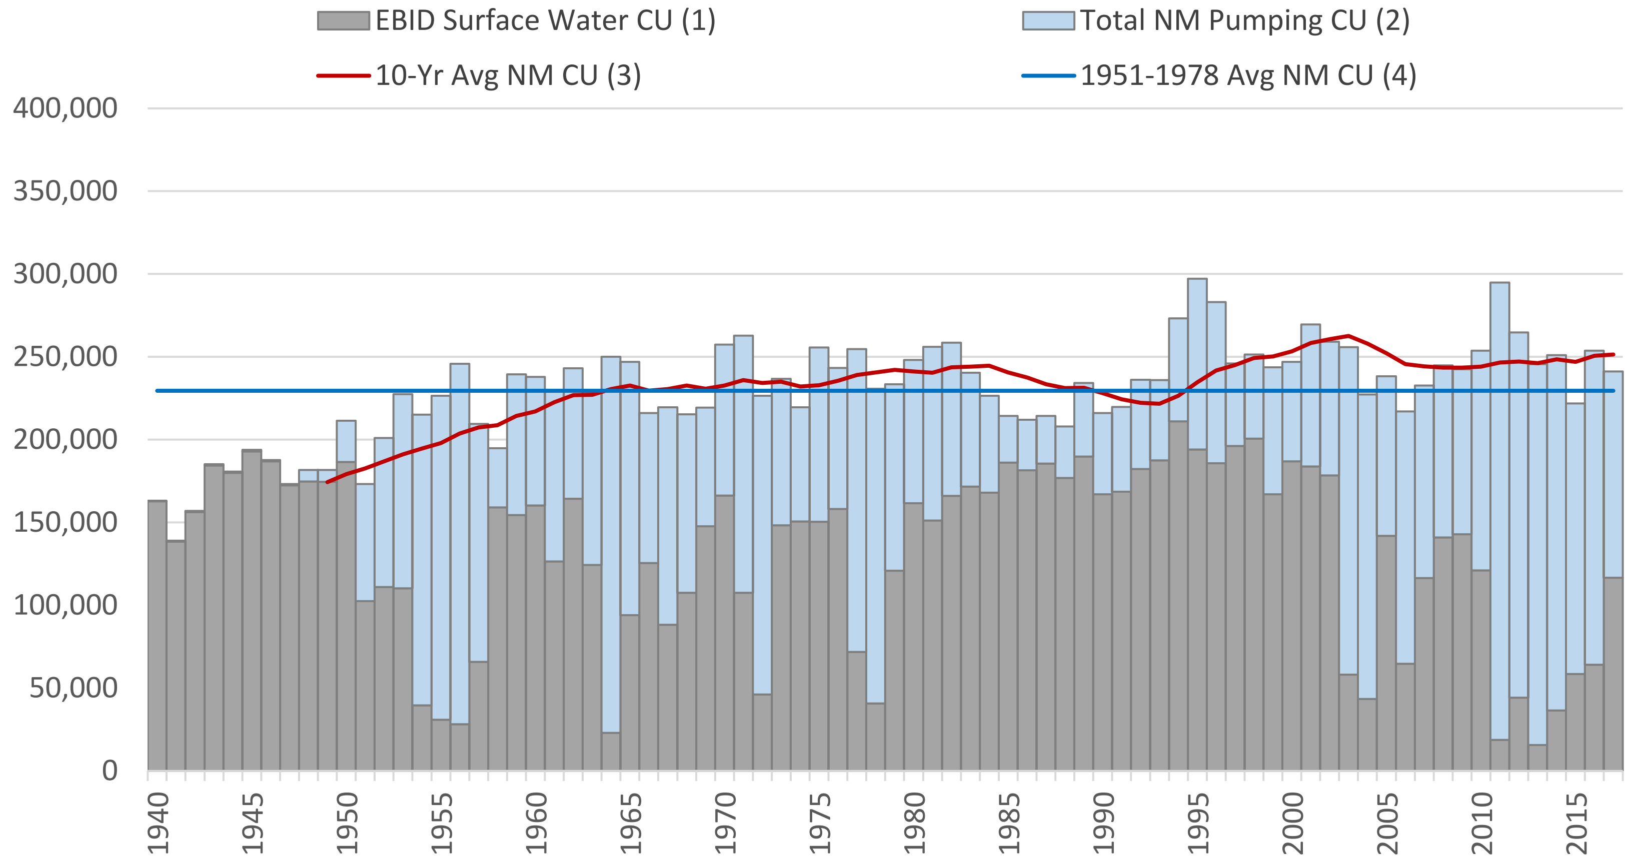
(2) Texas M&I pumping includes EPW and other Texas M&I pumping from NMR-M Model and Hueco Model.

Figure 19-9

Annual Irrigation and M&I Consumptive Use

New Mexico

1940 - 2017 (acre-feet)



Notes:

(1) EBID surface water irrigation consumptive use from SWE CFB Model.

(2) EBID irrigation pumping CU (incl. primary ground water lands) from SWE CFB Model plus New Mexico M&I pumping from NMR-M Model and Hueco Model minus return flows from NMR-M Model and Hueco Model inputs.

(3) 10-year running average of total irrigation and M&I consumptive use (1, 2).

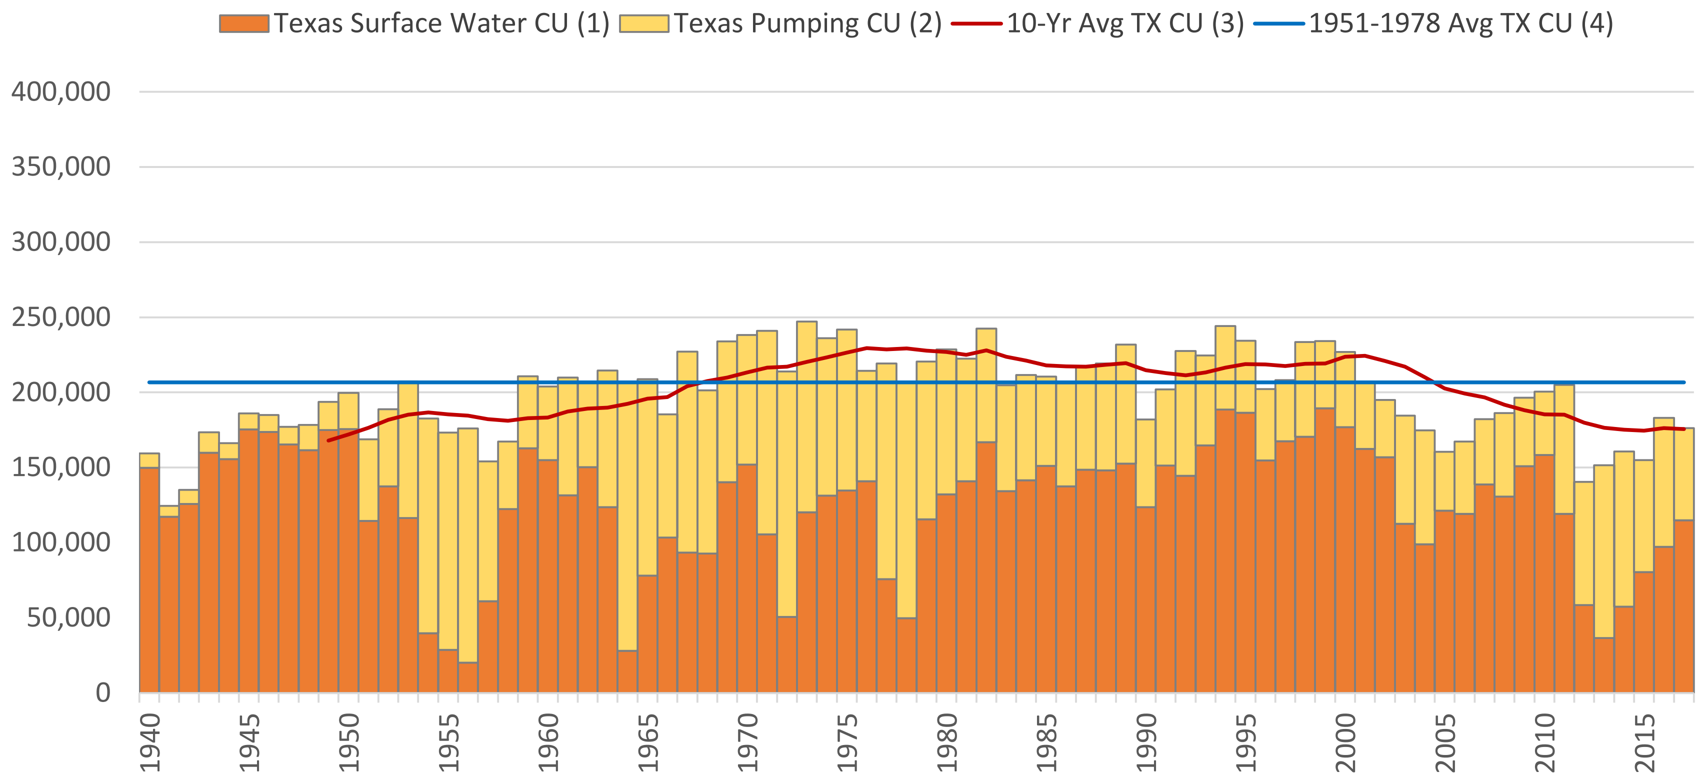
(4) 1951 - 1978 average of total irrigation and M&I consumptive use (1, 2).

Figure 19-10

Annual Irrigation and M&I Consumptive Use

Texas

1940 - 2017 (acre-feet)



Notes:

(1) Sum of EPCWID and HCCRD surface water irrigation consumptive use from SWE CFB Model plus EPW surface water diversions from SWE SWDataSet minus pro-rata return flows based on EPW total use minus total returns. EPW pumping and returns from NMR-M Model and Hueco Model.

(2) Sum of EPCWID and HCCRD irrigation pumping CU from SWE CFB Model plus Texas M&I pumping from NMR-M Model and Hueco Model minus return flows from NMR-M Model and Hueco Model inputs.

(3) 10-year running average of total irrigation and M&I consumptive use (1, 2).

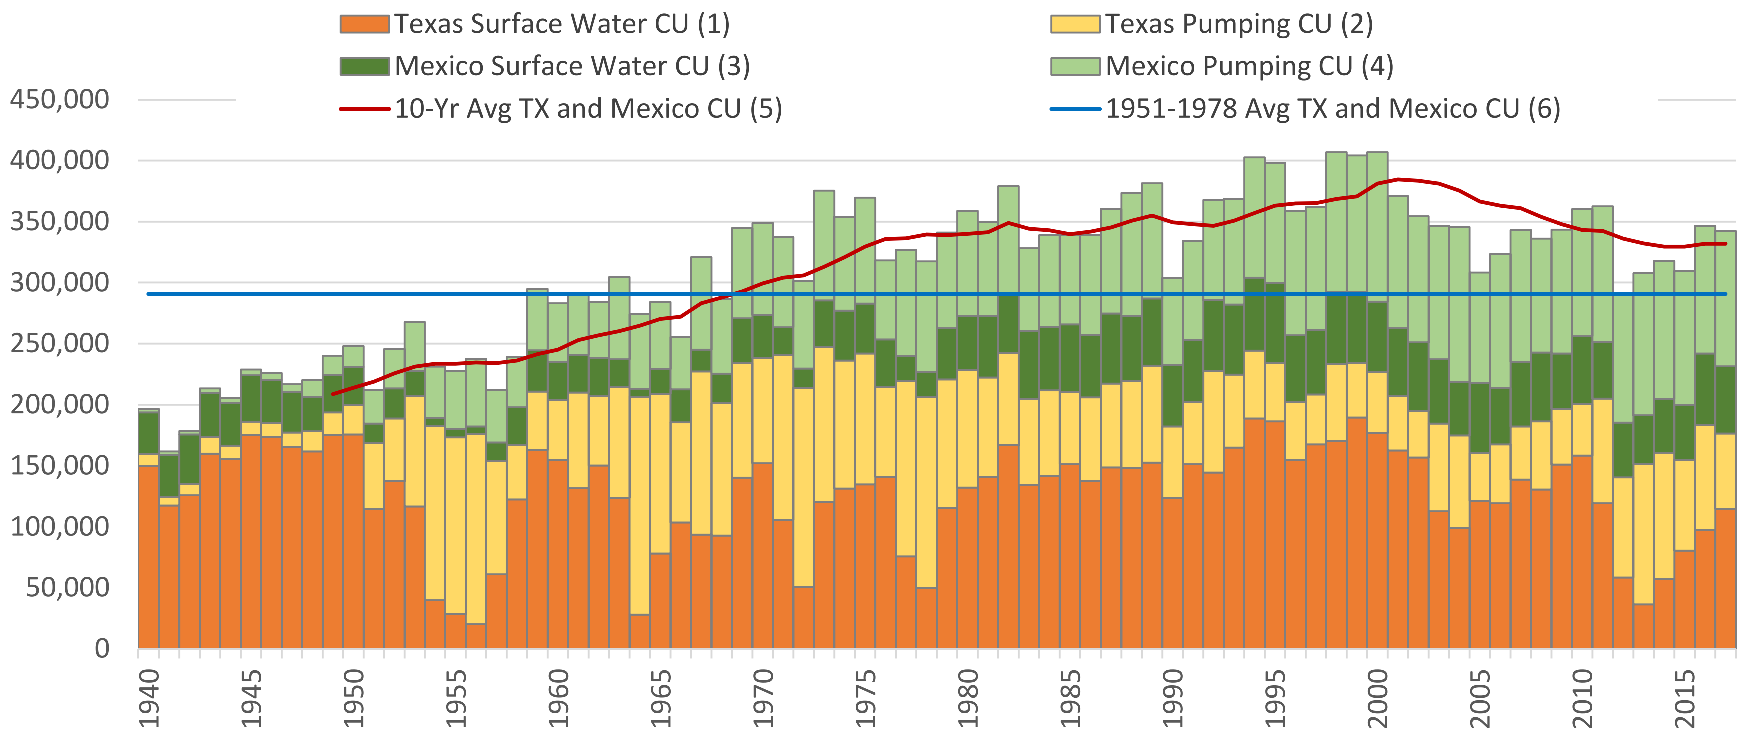
(4) 1951 - 1978 average of total irrigation and M&I consumptive use (1, 2).

Figure 19-11

Annual Irrigation and M&I Consumptive Use

Texas and Mexico

1940 - 2017 (acre-feet)



Notes:

(1) Sum of EPCWID and HCCRD surface water irrigation consumptive use from SWE CFB Model plus EPW surface water diversions from SWE SWDataSet minus pro-rata return flows based on EPW total use minus total returns. EPW pumping and returns from NMR-M Model and Hueco Model.

(2) Sum of EPCWID and HCCRD irrigation pumping CU from SWE CFB Model plus Texas M&I pumping from NMR-M Model and Hueco Model minus return flows from NMR-M Model and Hueco Model inputs.

(3) JID irrigation surface water consumptive use from SWE CFB Model.

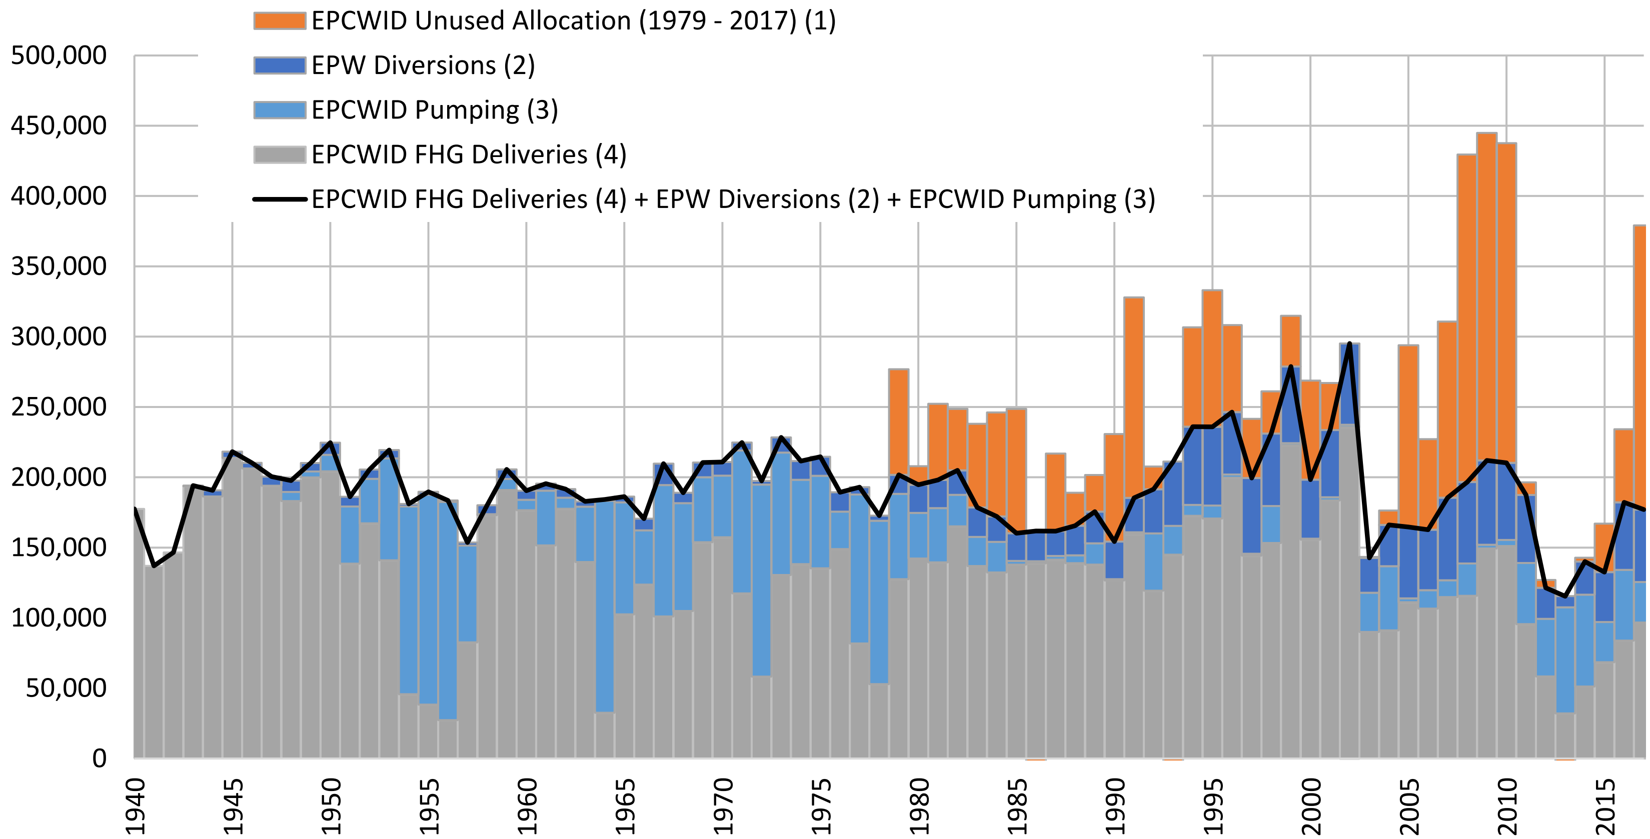
(4) Sum of JID irrigation pumping CU from SWE CFB Model and Ciudad Juarez M&I pumping (not including Conejos-Medanos M&I pumping) minus return flows from Hueco Model.

(5) 10-year running average of total Texas and Mexico consumptive use (1,2,3,4).

(6) 1951 - 1978 average of total Texas and Mexico consumptive use (1,2,3,4).

Figure 19-12

Annual EPCWID FHG Deliveries, Pumping, and Unused Allocation
1940 - 2017 (acre-feet)



Notes:
(1) EPCWID unused allocation from SWE Accounting Dataset and computed as allocations minus diversion charge.
(2) EPW diversions from SWE SWDataSet.
(3) EPCWID pumping from SWE CFB Model.
(4) EPCWID FHG deliveries from SWE CFB Model.

Figure 19-13

Schematic Diagram
EPCWID Distribution and Drainage System and Gages

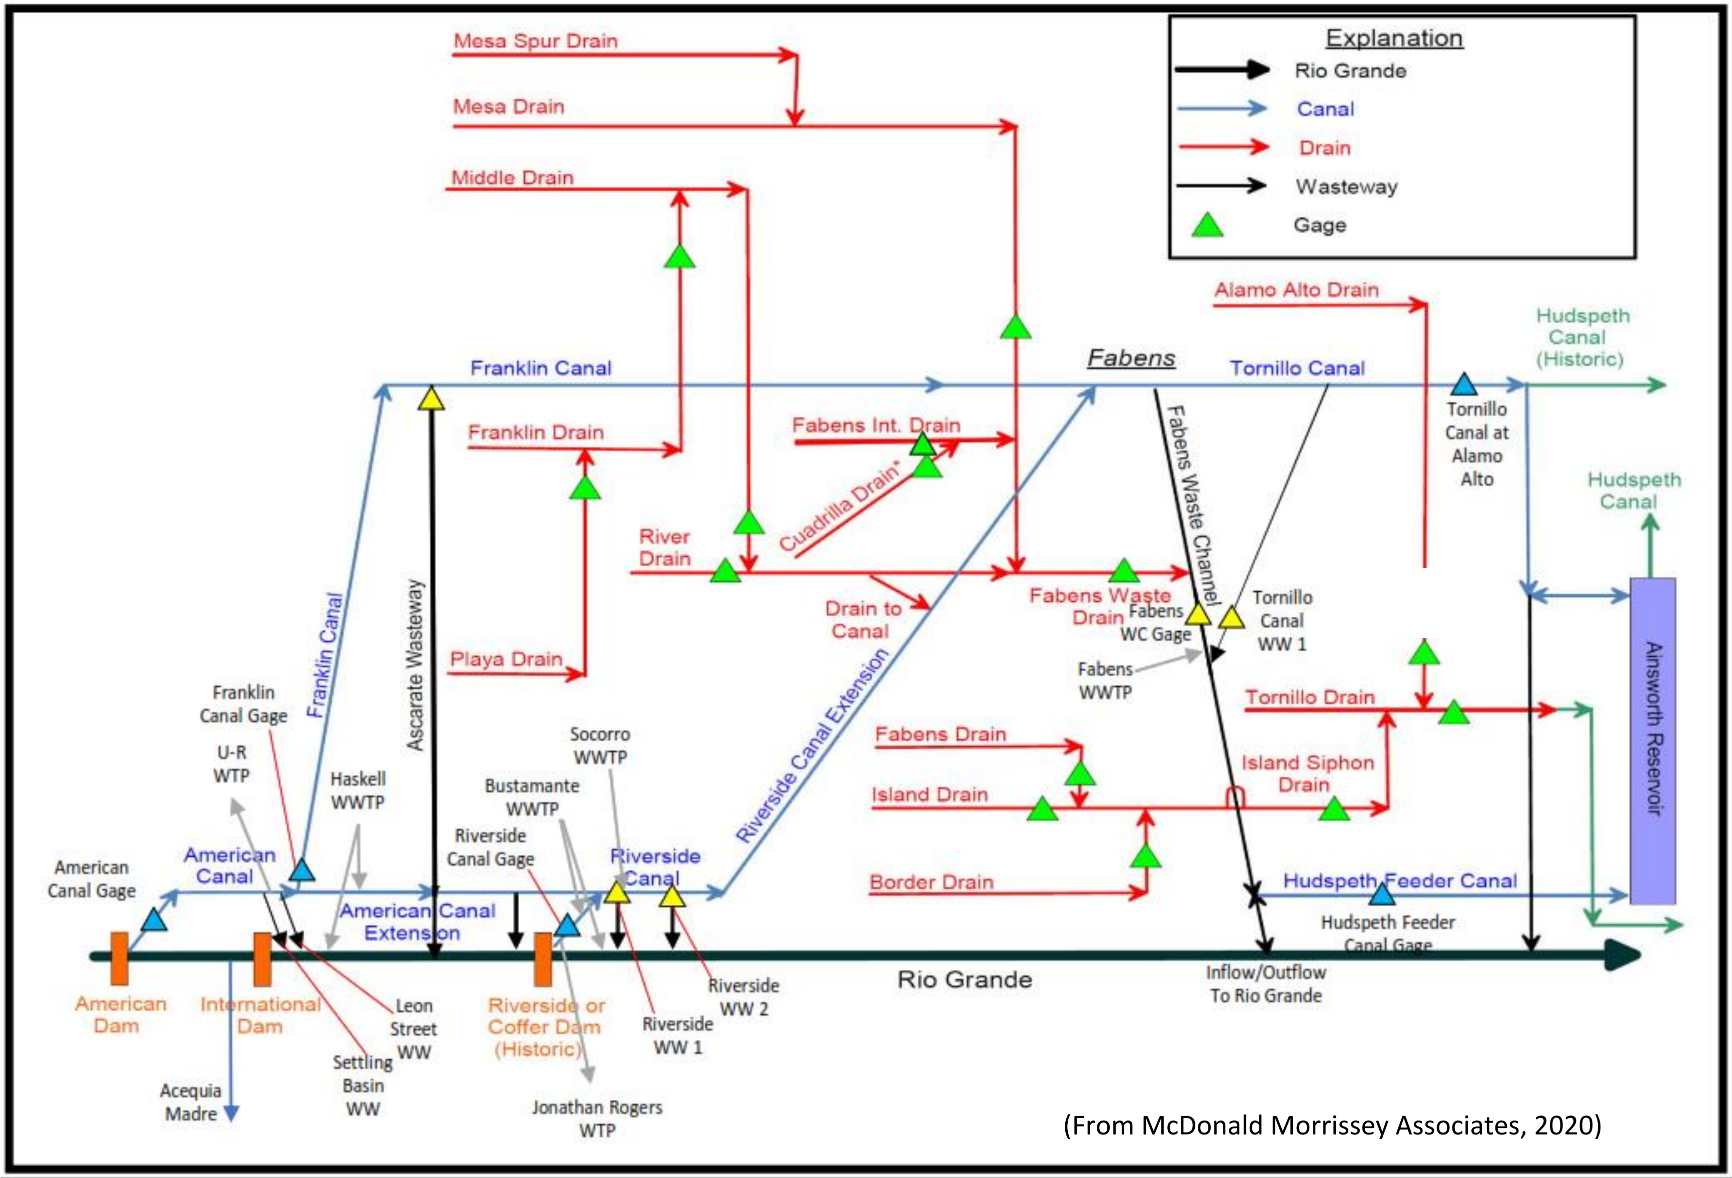


Figure 19-14

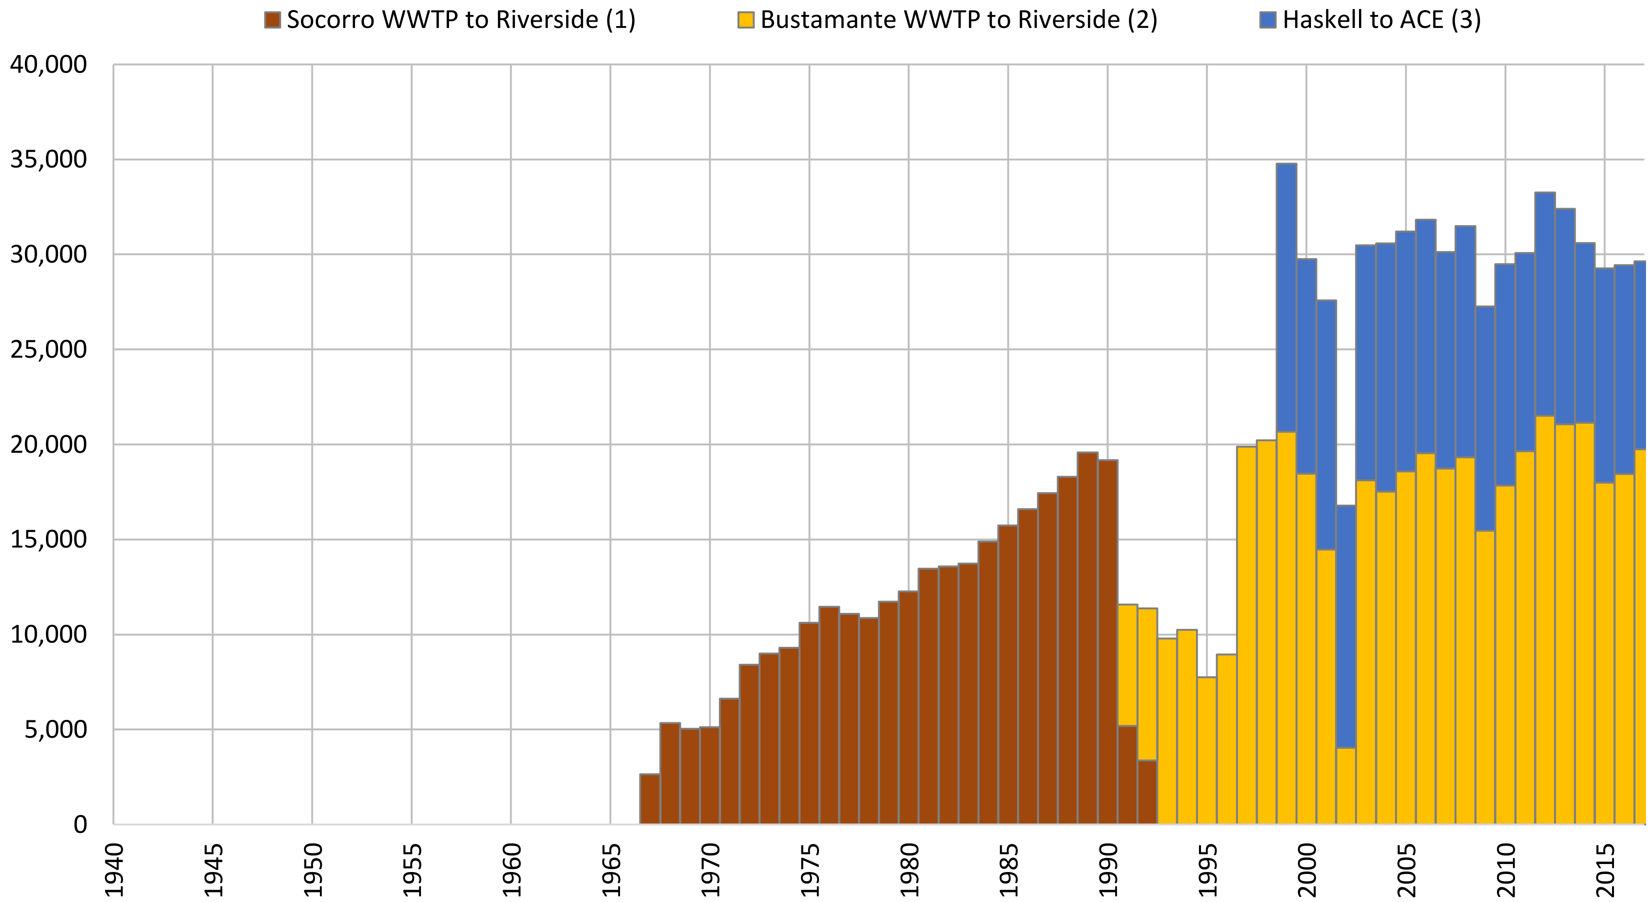
WWTP Discharges to Canals (Irrigation Season)
EPCWID (El Paso Valley)
1967 - 2017 (acre-feet)



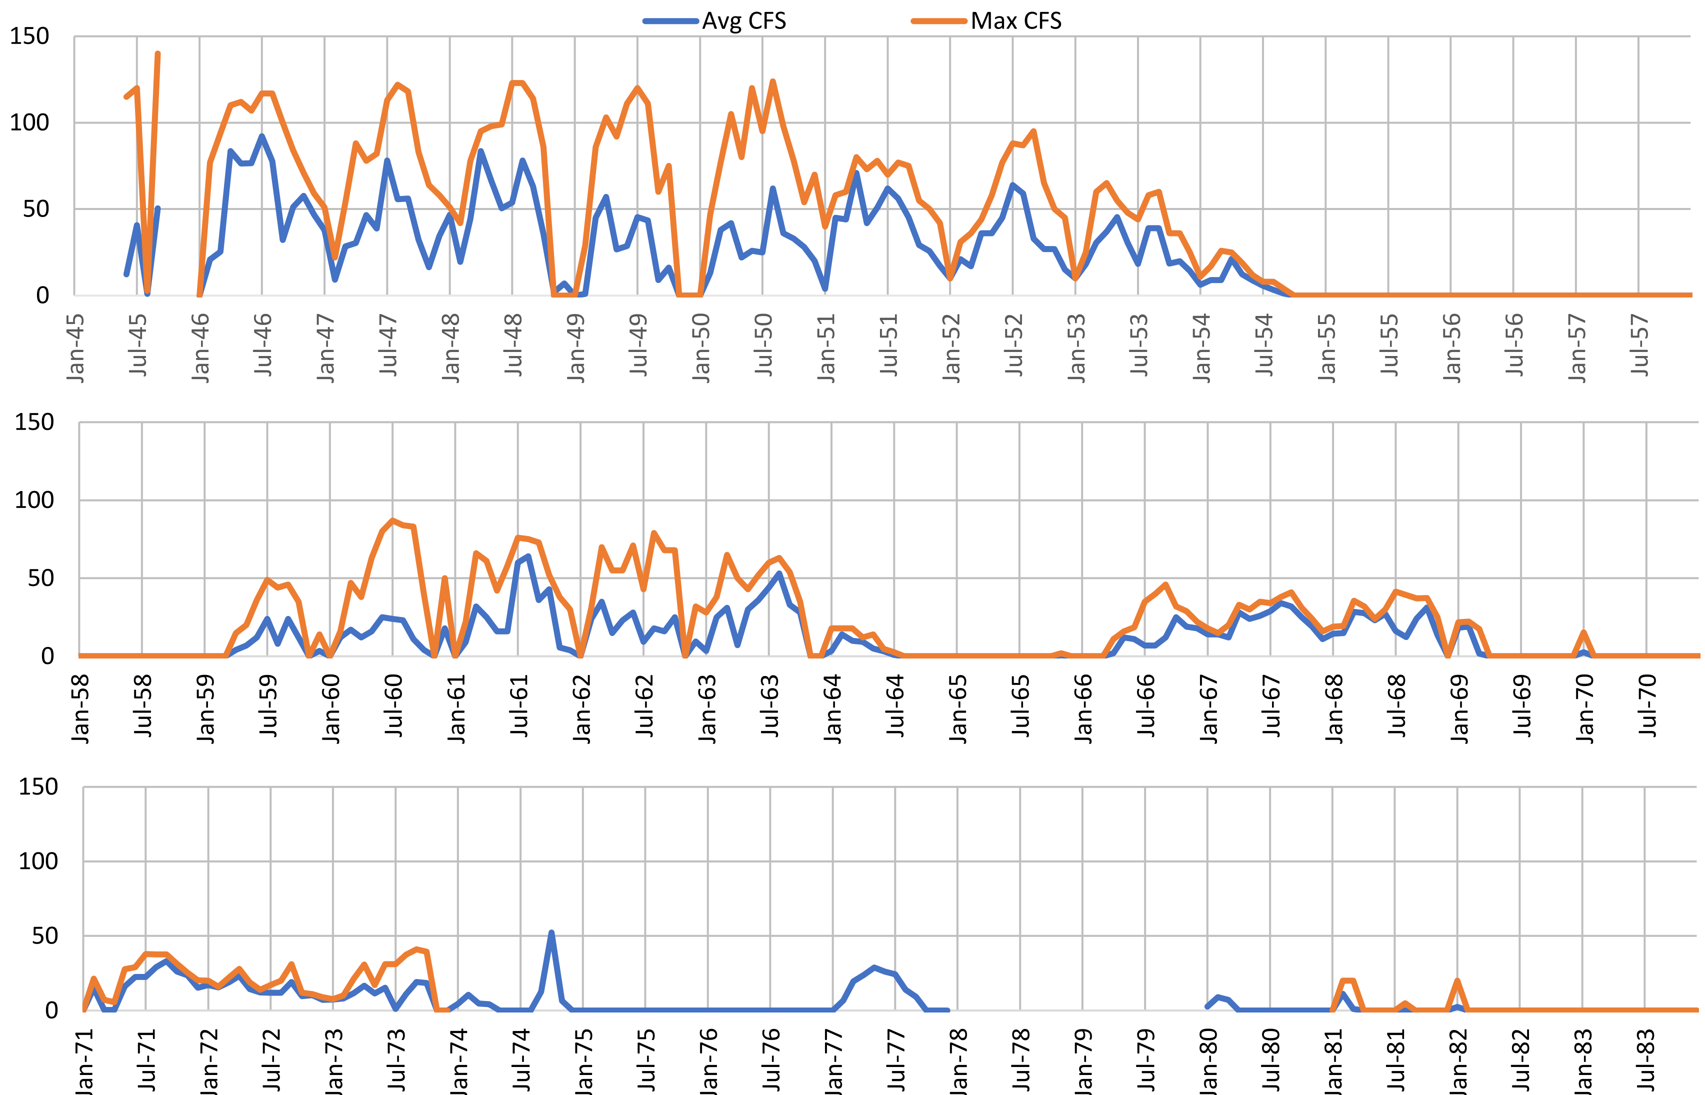
Notes:

(1) Monthly Socorro WWTP discharges estimated 1967 - 1988 from SWE SWDataSet (annual data only 1967 - 1984).
(2) Bustamante WWTP discharges to Riverside Canal estimated 1991 - 1994 from SWE SWDataSet.
(3) Haskell WWTP discharges to the American Canal Extension ("ACE") are included in Riverside Canal gaged flows from SWE SWDataSet.

Figure 19-15

Monthly Drain Flows Pumped at Fabens to Canal

1945 - 1983 (CFS)

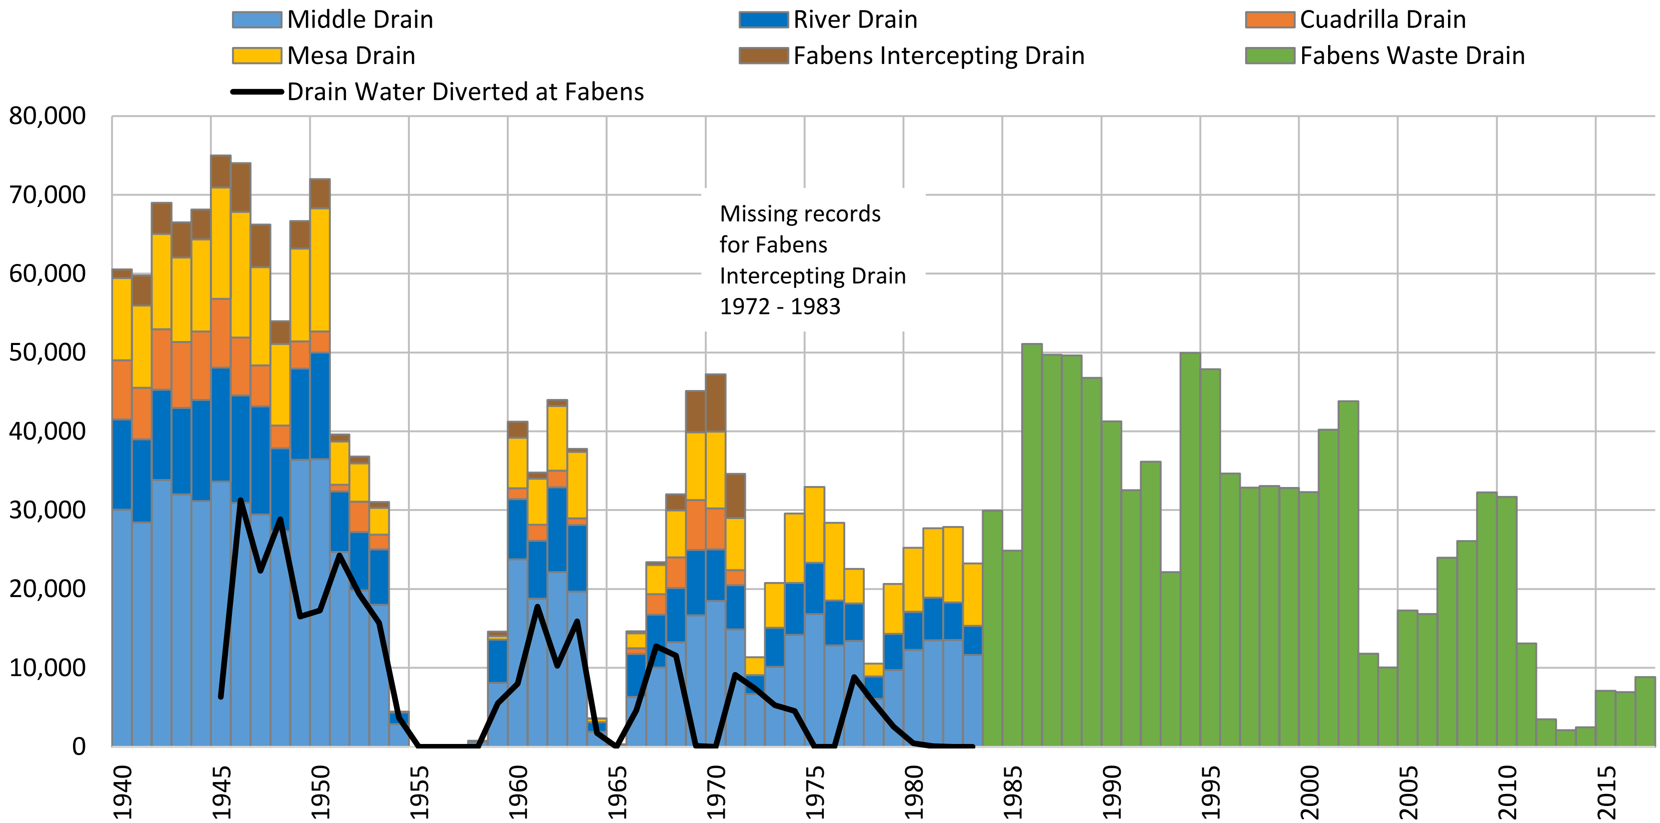


Note:

(1) Monthly average and maximum daily values from USBR daily records ("USBR-Scan-Drain to Canal").

Figure 19-16

Irrigation Season Drain Flows at Fabens
EPCWID (El Paso Valley)
1940 - 2017 (acre-feet)



Notes:

(1) Water pumped from the River Drain and Middle Drain for EPCWID irrigation use.

(2) The Mesa Drain, Cuadrilla Drain, and Fabens Intercepting Drain reportedly were reportedly not used for EPCWID irrigation use. These drain flows accrue to the Fabens Waste Channel and become part of the HCCRD supply along with unused River and Middle Drain flows.

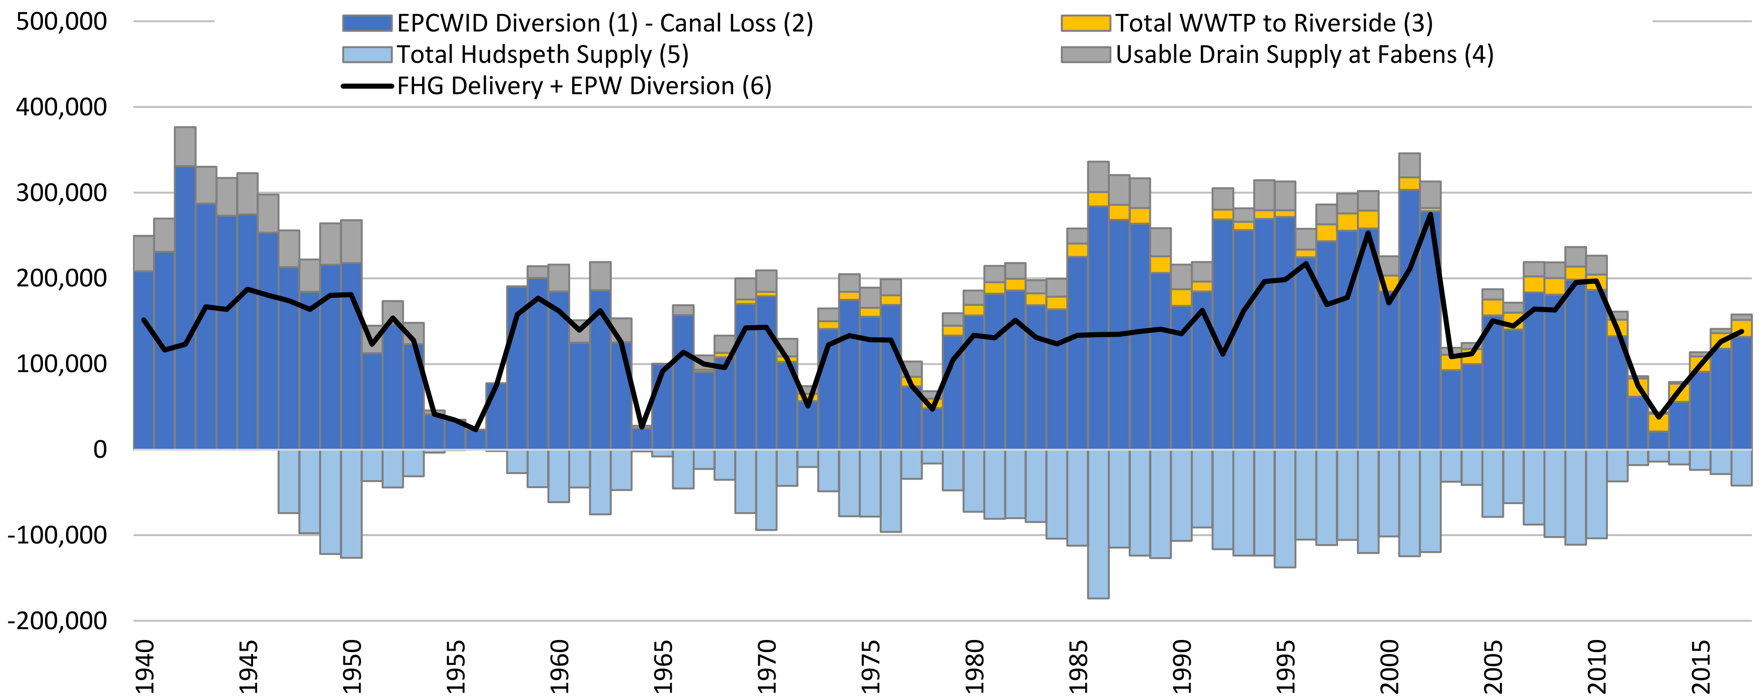
(3) The Fabens Waste Drain collects flow from the River Drain, Middle Drain, Mesa Drain, Cuadrilla Drain, and Fabens Intercepting Drain for delivery into the Fabens Waste Channel.

(4) A schematic diagram illustrating EPCWID drain system is provided in **Figure 19-13**.

(5) Fabens Waste Drain flows were estimated in 1992 and some months in 1993 - 1996, 2003, and 2012.

Figure 19-17

Available FHG Supply vs. FHG Delivery (Irrigation Season)
EPCWID (El Paso Valley)
1940 - 2017 (acre-feet)



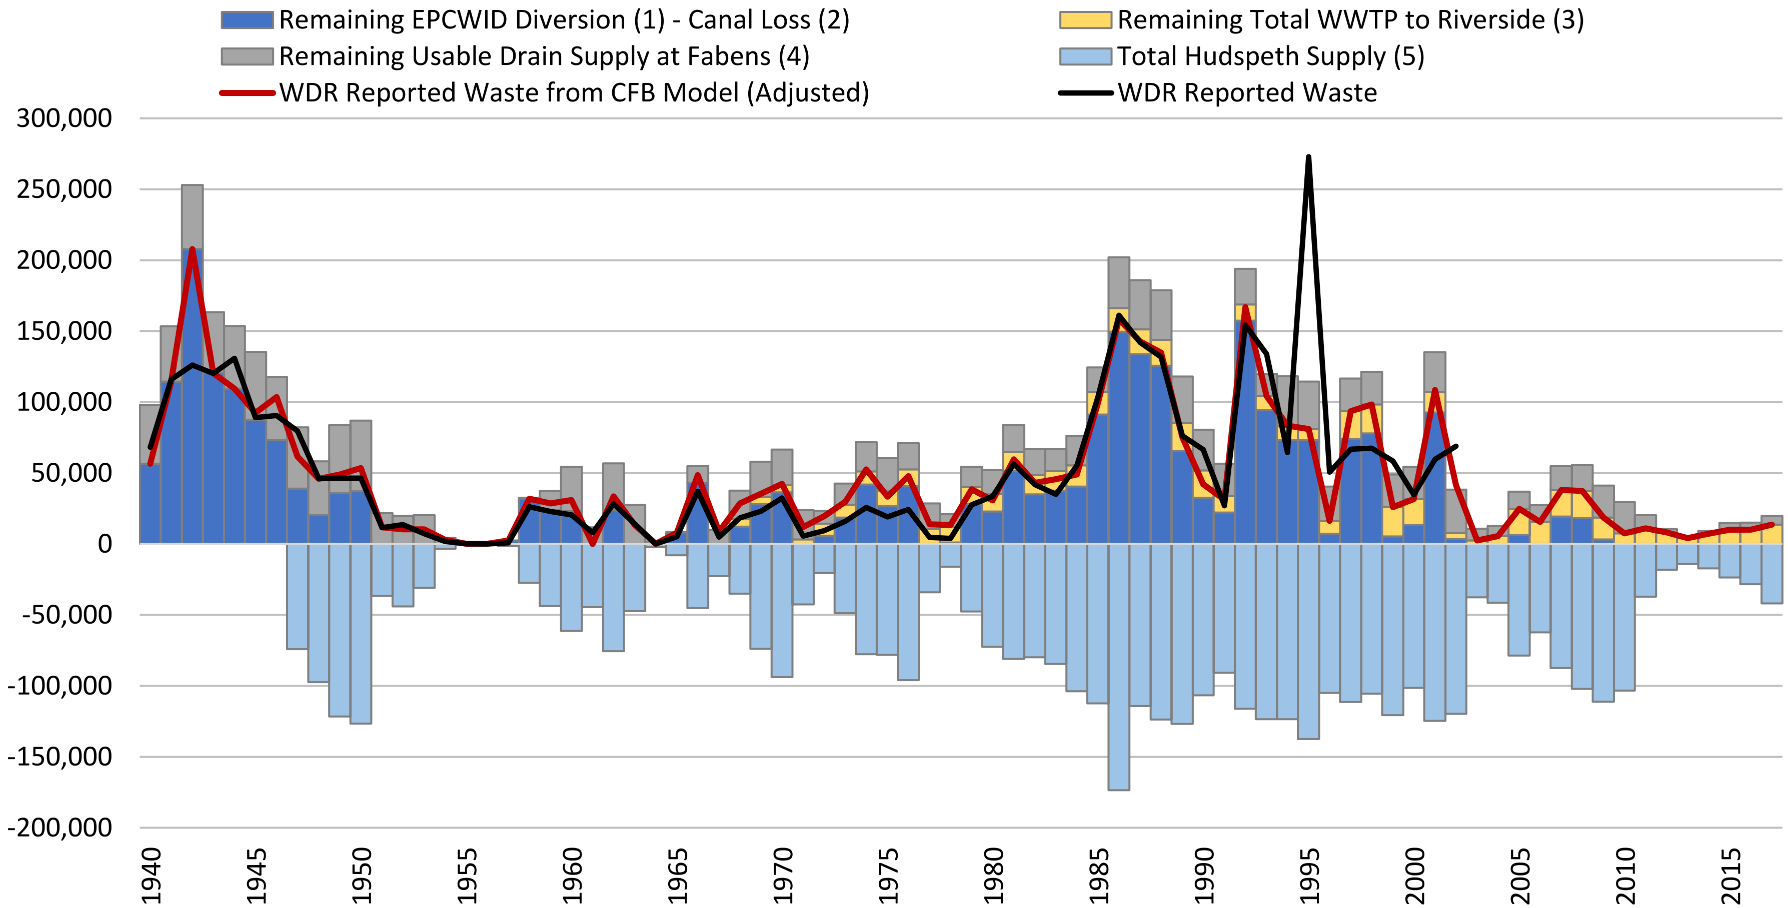
Notes:

All data from SWE SWDataSet unless otherwise noted.

(1) EPCWID (El Paso Valley) Diversions computed as the sum of the Franklin Canal plus Riverside Canal plus EPW diversions minus Ascarate Wasteway.
(2) Canal Loss from SWE CFB Model and are based on records and estimates for years with no records.
(3) Total WWTP to Riverside includes Socorro WWTP and Bustamante WWTP. Flows are estimated for Socorro WWTP from 1985 - 1988 and for Bustamante WWTP from 1991 - 1994.
(4) Usable Drain Supply at Fabens computed as the sum of the River Drain plus Middle Drain (1940 - 1983) and 70% of Fabens Waste Drain (1984 - 2017). Fabens Waste Drain flows were estimated in 1992 and some months in 1993 - 1996, 2003, and 2012.
(5) Total Hudspeth Supply is the sum of Tornillo Drain plus Tornillo Canal at Alamo Alto plus Hudspeth Feeder Canal. Missing records for Tornillo. Canal at Alamo Alto in 1995 - 1996 and Hudspeth Feeder Canal in 2011 - 2012 were estimated. Missing records for Tornillo Drain in 2011 - 2012 were not estimated. Total Hudspeth Supply shown as negative for presentation purposes.
(6) FHG Delivery from SWE CFB Model based on records and estimates for years with no records plus EPW Diversions.

Figure 19-18

Waste Comparison (Irrigation Season)
EPCWID (El Paso Valley)
1940 - 2017 (acre-feet)



Notes:

(1,2,3) The positive bars represent the portion of the available EPCWID supply in excess of the historical EPCWID FHG deliveries (see Figure 19-17).

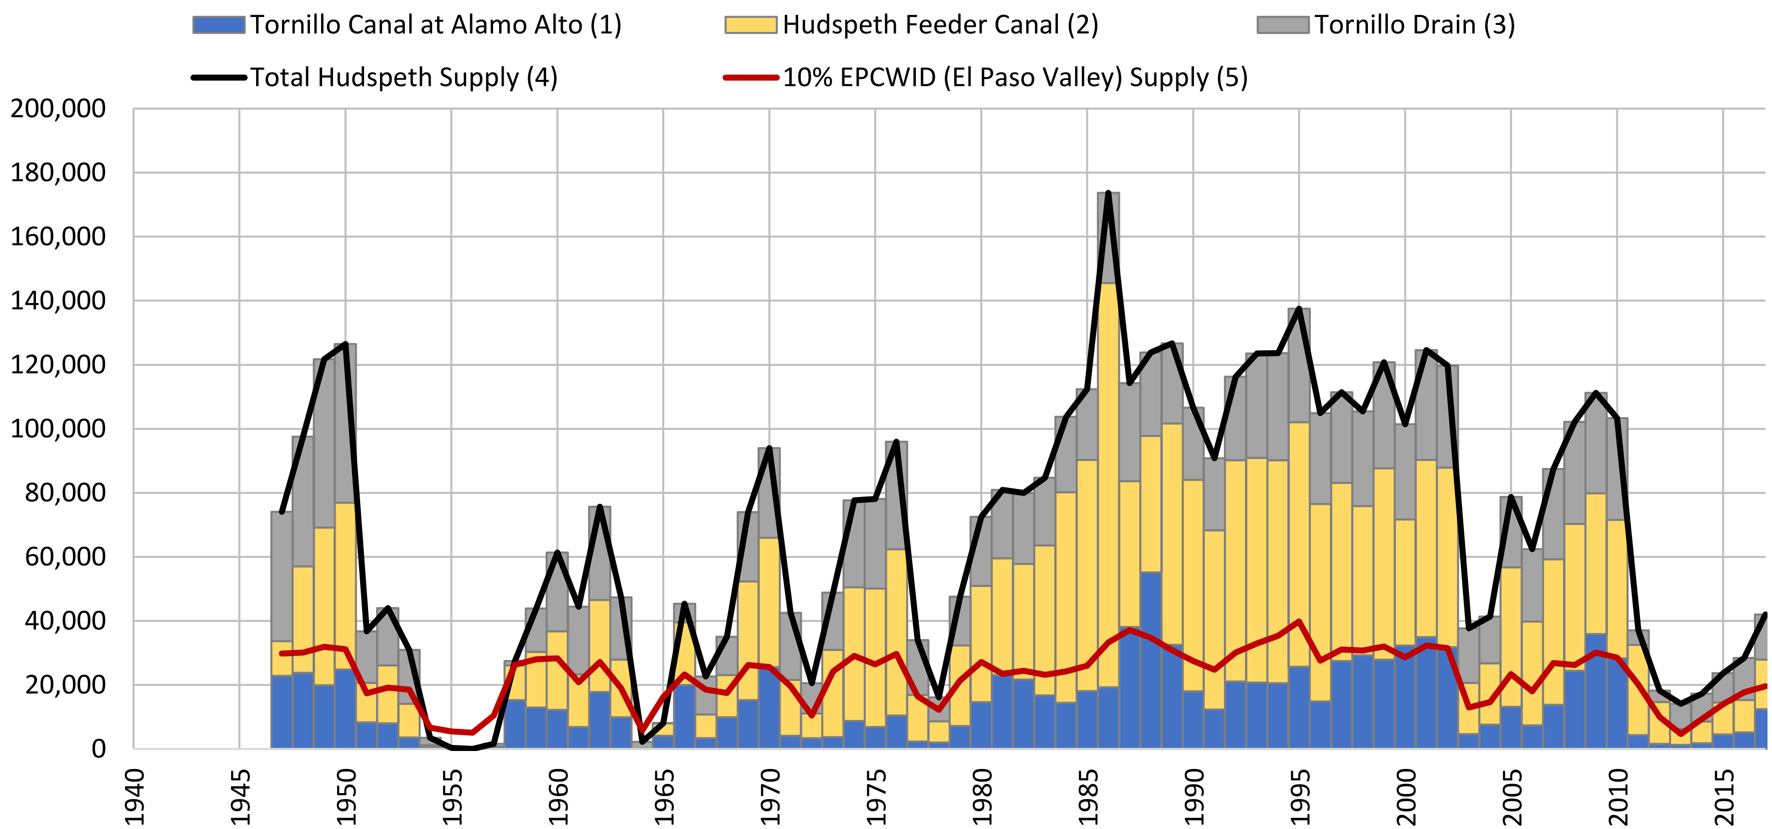
(4) Total Hudspeth Supply is the sum of Tornillo Drain plus Tornillo Canal at Alamo Alto plus Hudspeth Feeder Canal (data from 1947 - 2017 only).

(5) Adjusted WDR Reported Waste is the historical reported waste from the WDRs with mass balance adjustments and estimates of missing data from SWE CFB Models.

(6) WDR Reported Waste (Unadjusted) is the historical reported waste from the SWE Accounting DataSet.

Figure 19-19

Total Water Supply (Irrigation Season)
HCCRD
1947 - 2017 (acre-feet)

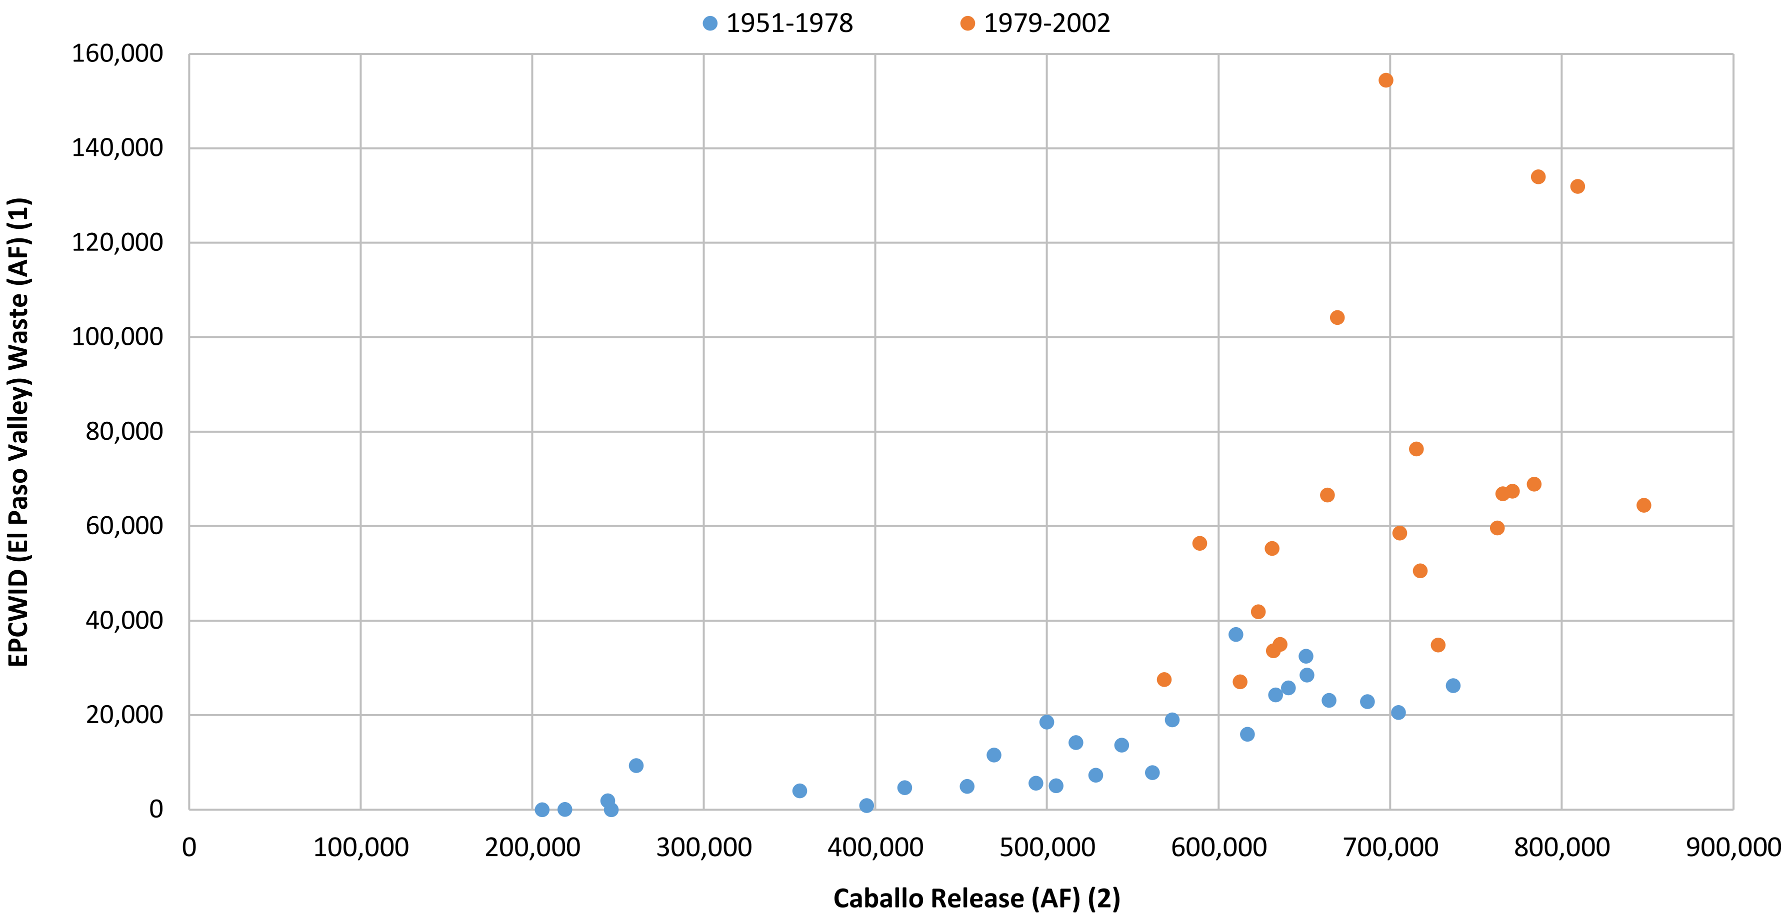


Notes:

Prior to 1947, the Hudspeth Feeder Canal did not exist and there was no Tornillo Canal at Alamo Alto gage.

(1) Tornillo Canal at Alamo Alto flows include estimates for certain months in 1995 and 1996; data and estimates from SWE SWDataSet.
(2) Hudspeth Feeder Canal flows include estimates for certain months in 2011 and 2012; data and estimates from SWE SWDataSet.
(3) Tornillo Drain flows are incomplete for 2011 and 2012; data from SWE SWDataSet and estimates from the SWE CFB Model.
(4) Total Hudspeth Supply is the sum of Tornillo Canal at Alamo Alto (1) plus Hudspeth Feeder Canal (2) plus Tornillo Drain (3) flows.
(5) EPCWID (El Paso Valley) Supply computed as the sum of the Franklin Canal plus Riverside Canal flows plus EPW surface water diversions minus Ascarate Wasteway flows; flows from SWE SWDataSet.

Figure 19-20
Waste vs. Caballo Release (Irrigation Season)
EPCWID (El Paso Valley)
1951 - 2002 (acre-feet)

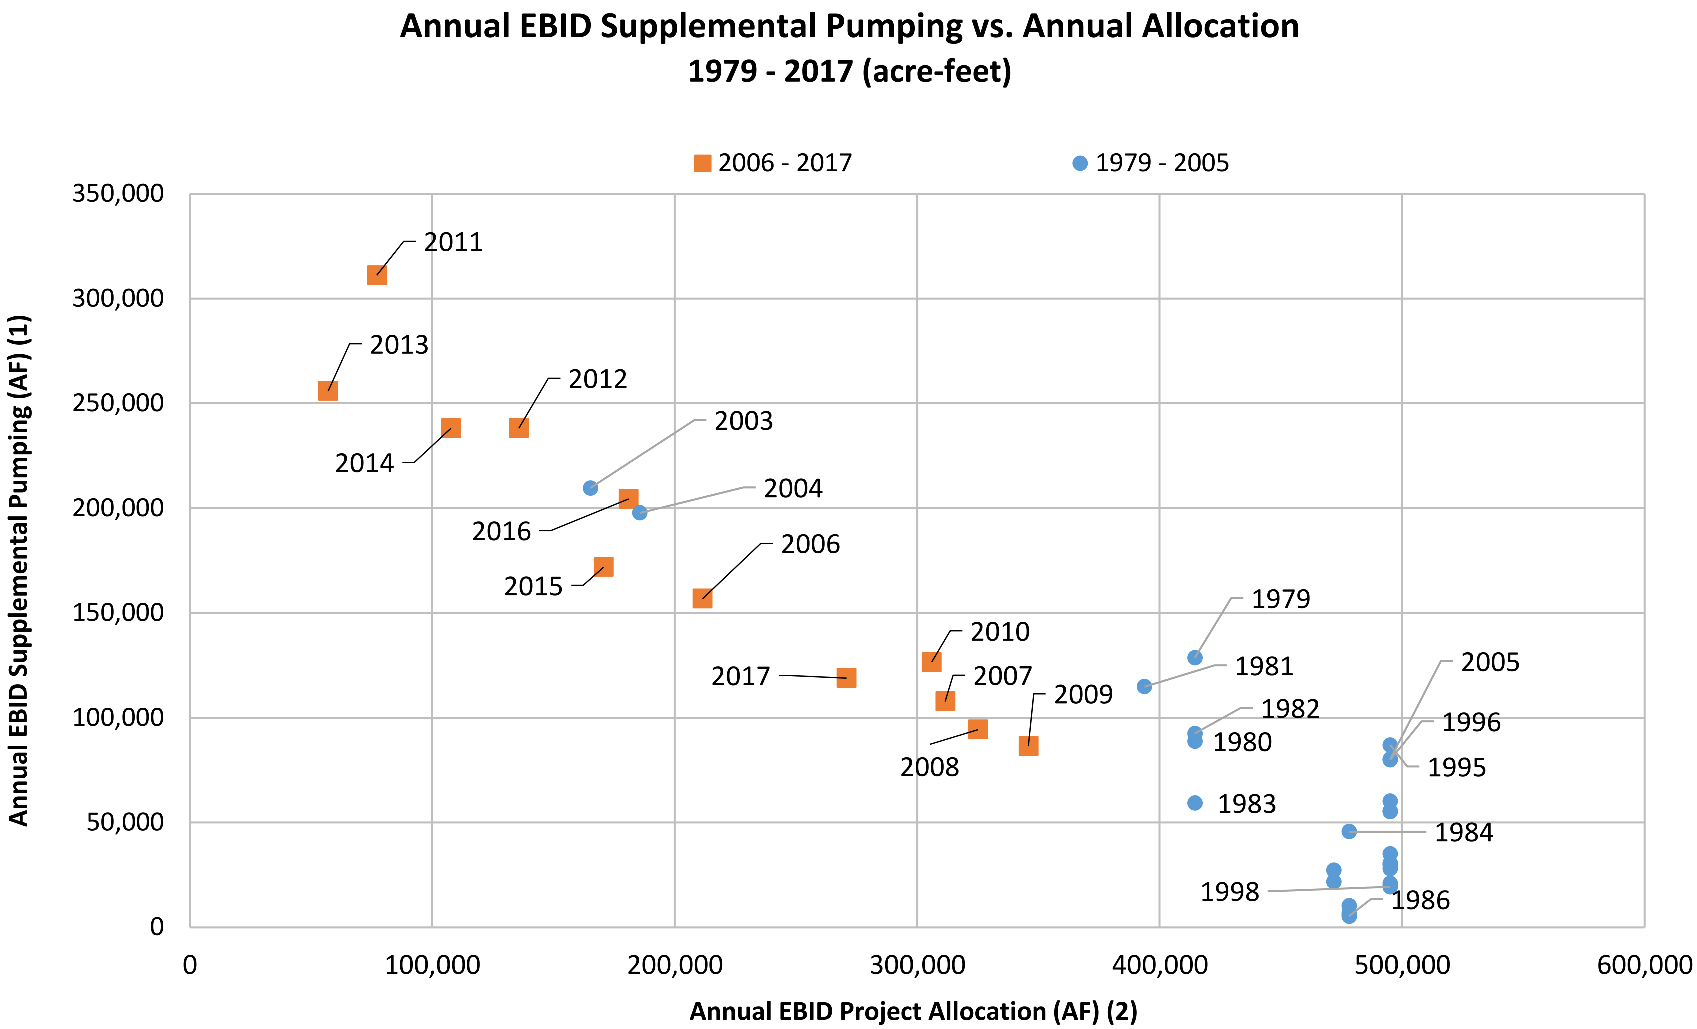


Notes:

(1) EPCWID (El Paso Valley) Waste from Water Distribution Reports in the SWE Accounting DataSet.

(2) Caballo Releases are the Rio Grande below Caballo flows from SWE SWDataSet.

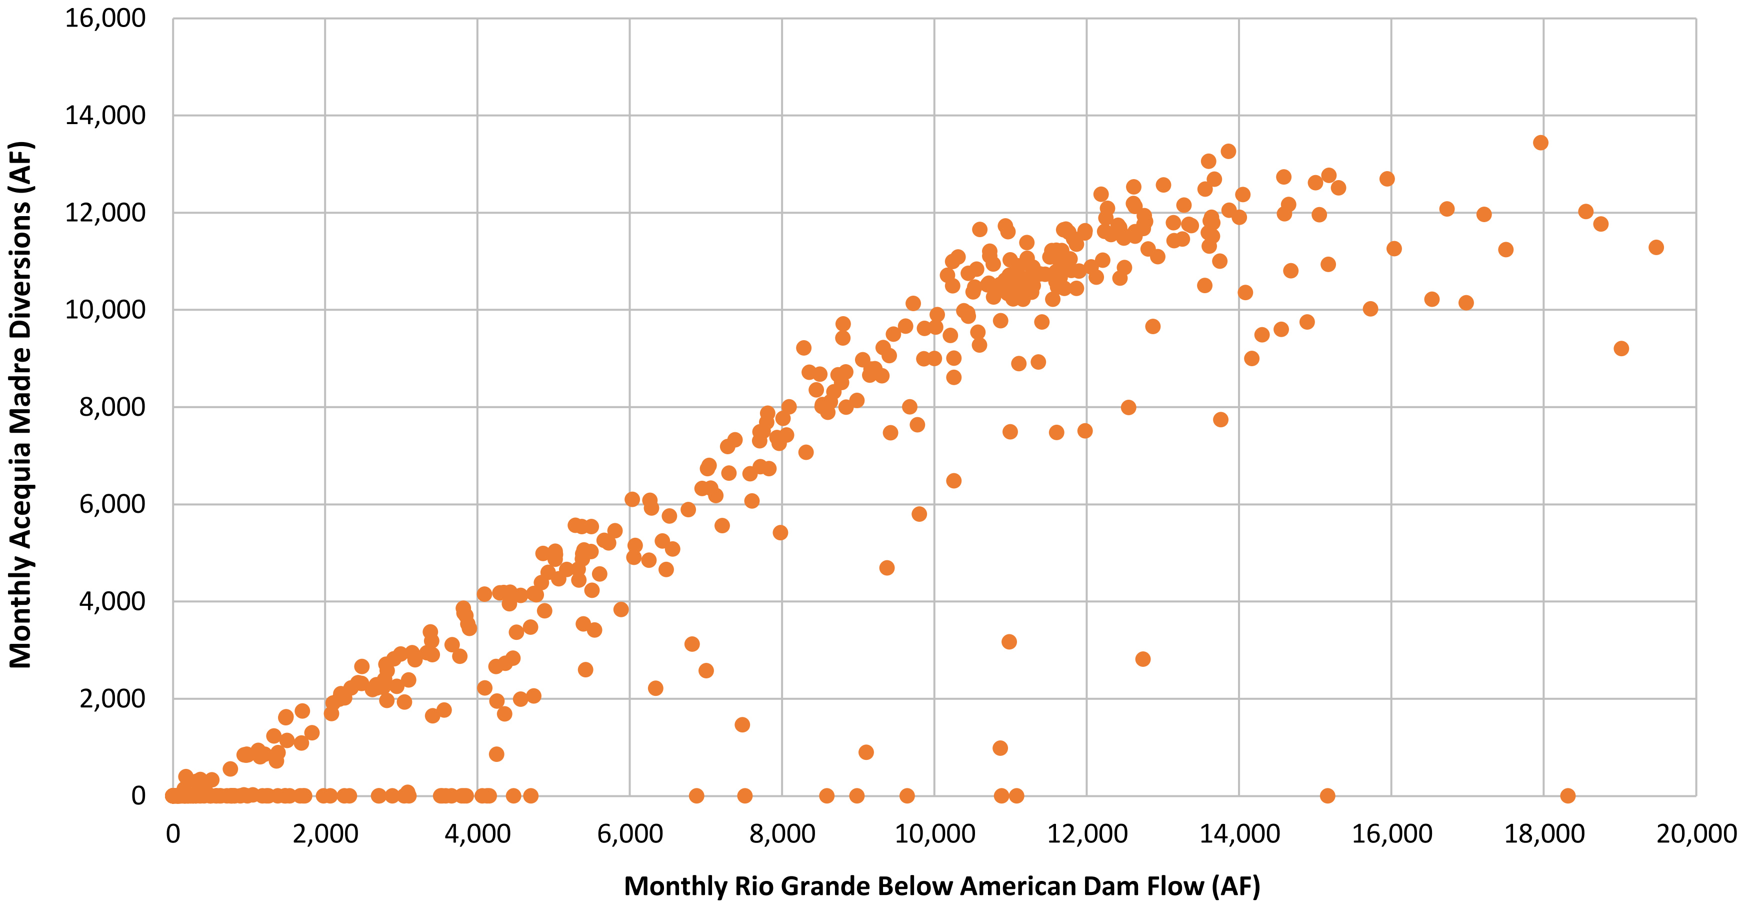
Figure 19-21



Notes:
(1) Supplemental irrigation pumping amounts from SWE CFB Model.
(2) Annual allocations and diversion charges from SWE Accounting DataSet.

Figure 19-22

Monthly Acequia Madre Diversions vs. Monthly Rio Grande Below American Dam Flows
1940 - 2017 (acre-feet)

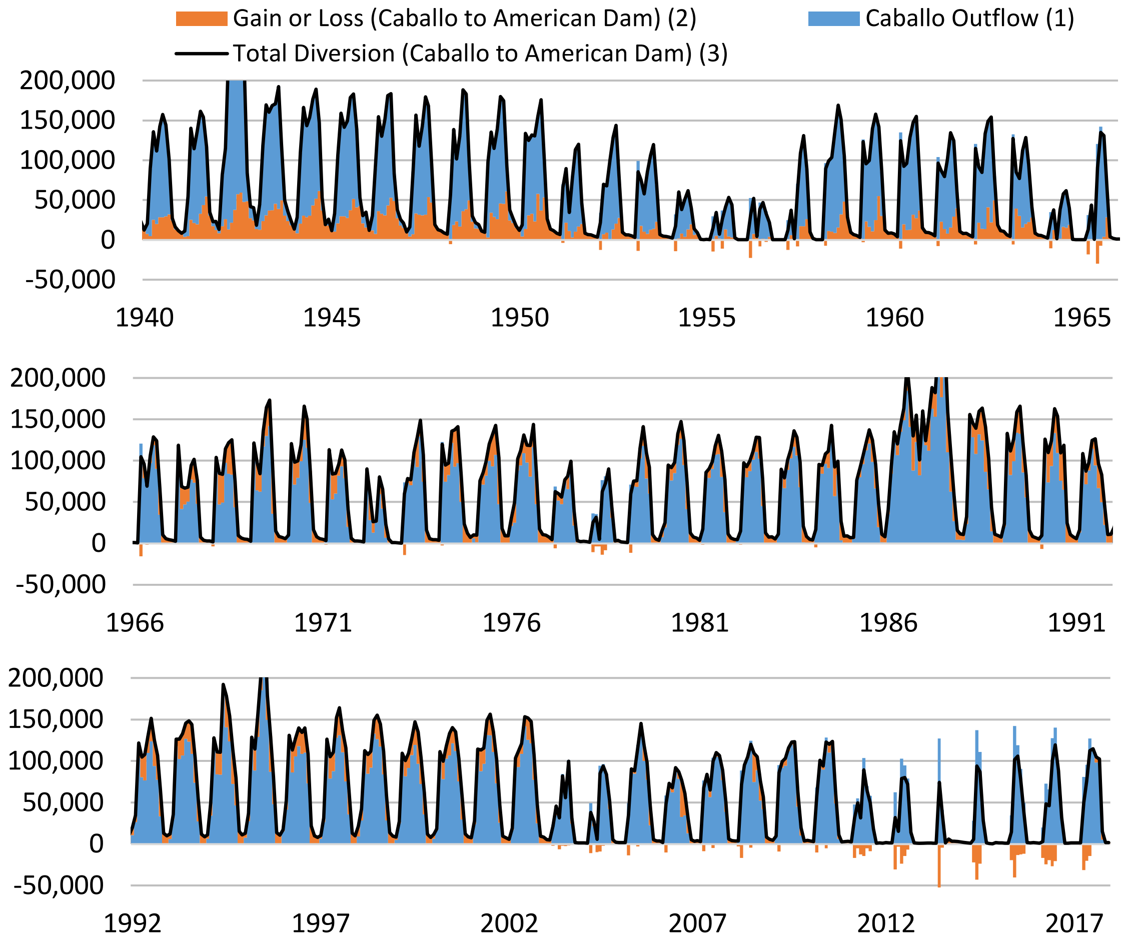


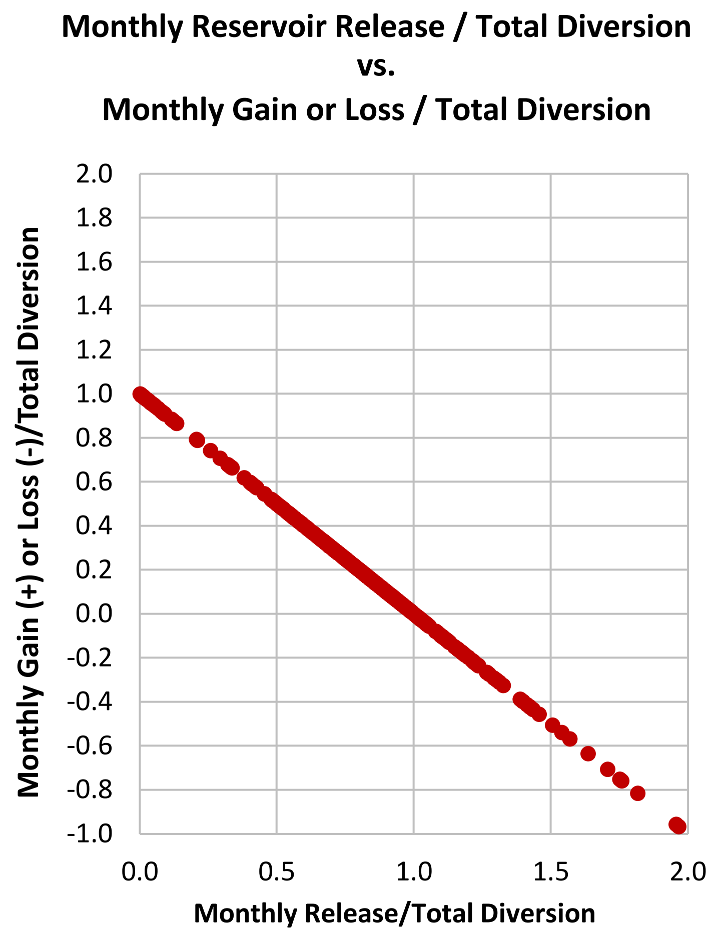
Note:
(1) No monthly data for 2007 (only annual data available).
(2) Monthly flow data from SWE SWDataSet.

7/15/2020

Figure 19-23

Monthly Reservoir Releases, Diversions, and Gains or Losses
Below Caballo Dam to Below American Dam
1940 - 2017 (acre-feet)





Notes:

Monthly flow data from SWE SWDataSet.

(1) Caballo releases from Rio Grande below Caballo Dam gage.

(2) Monthly gain or loss computed as total diversions plus Rio Grande below American Dam flow minus Caballo Reservoir releases.

(3) Total diversions at Arrey Dam (Arrey Canal and Percha Lateral), Leasburg Dam (Leasburg Canal, California Extension, and Pumped from River), Mesilla Dam (Eastside Canal, Westside Canal, and Del Rio Lateral), and American Canal PLUS Rio Grande below American Dam flow.

7/15/2020

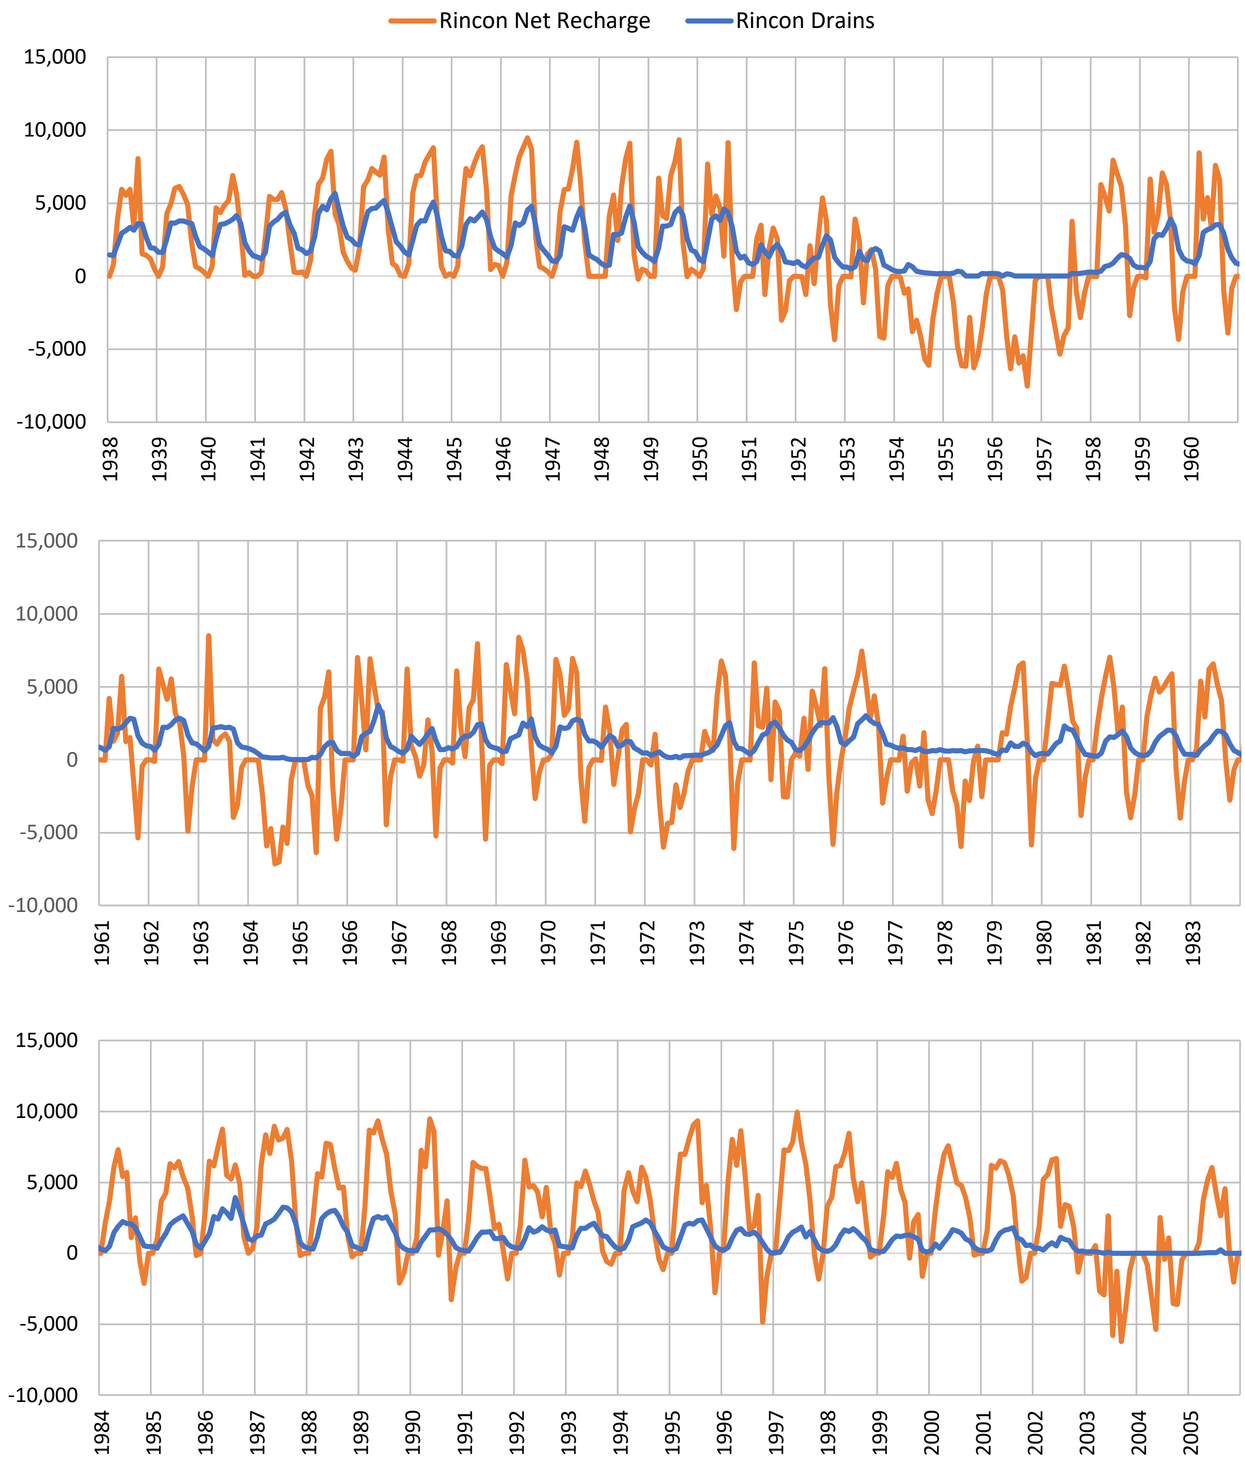
Figure 20-1
Total Consumptive Use of Irrigation Water
Rincon and Mesilla Valleys (EBID and EPCWID)
SWE Canal and Farm Budget Model

	CIR (acre-feet/acre)					Consumptive Use (acre-feet)		
	EBID Rincon		EBID Mesilla		EPCWID Mesilla	EBID	EPCWID	R-M
Period	Suppl	Primary	Suppl	Primary	Total	Total	Total	Total
(1) 1938-1950	2.35	2.69	2.36	2.71	2.35	173,395	15,436	188,830
(2) 1985-2016	2.74	2.91	2.78	2.95	2.61	223,057	13,858	236,916
(3) 1985-2016 (adj)	2.35	2.69	2.36	2.71	2.35	191,301	12,461	203,763
Ratio (1)/(2)	0.86	0.92	0.85	0.92	0.90			

Notes:
(1,2) CIR and consumptive use of irrigation water from SWE CFB Model.
(3) CU is adjusted for 1985-2016 by multiplying monthly CIR by the ratio of CIR: (1) 1938-1950 average/(2) 1985 - 2016 average.

Figure 23-1

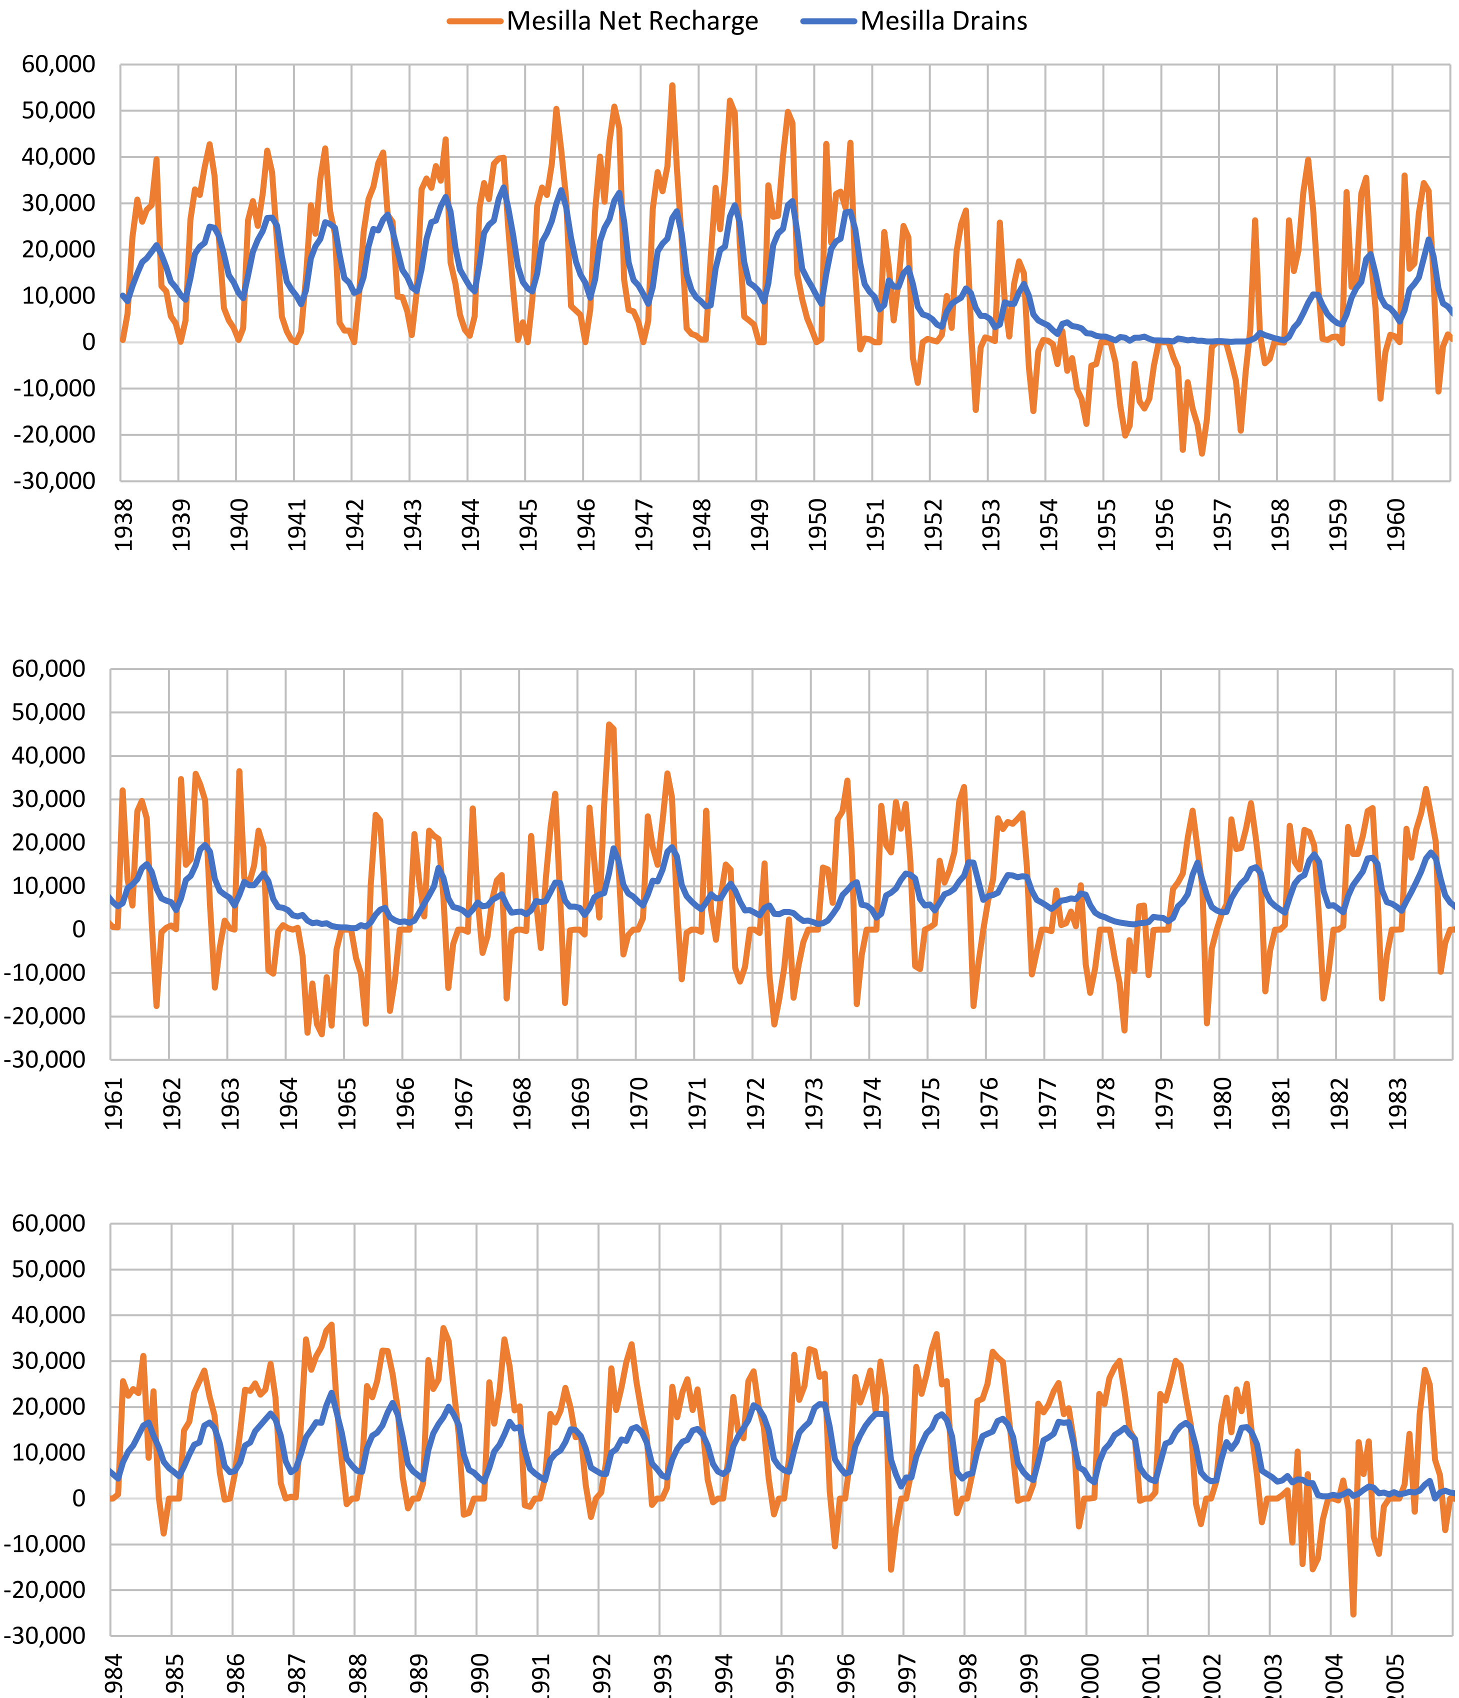
Monthly Net Recharge vs. Drain Flow
Rincon Valley
1938 - 2005 (acre-feet)



Notes: Net recharge computed as canal seepage + on farm deep percolation minus pumping from the SWE Canal and Farm Budget Model of the Rincon Valley.
Drain flows are the sum of the reported flows of the Rincon Valley drains.
Angostrata drain data is unavailable from 1983-2005.
Rincon drain data is unavailable from 2006-2017.

Figure 23-2

Monthly Net Recharge vs. Drain Flow
Mesilla Valley
1938 - 2005 (acre-feet)



Notes: Net recharge computed as canal seepage + on farm deep percolation minus pumping from the SWE Canal and Farm Budget Model of the Leasburg-Mesilla Valley (NM + TX). Drain flows are the sum of the reported flows of the Mesilla Valley drains. Drain data availability varies by drain.

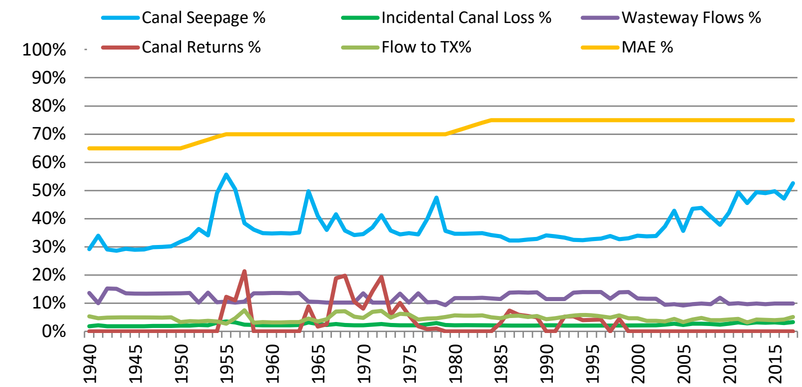
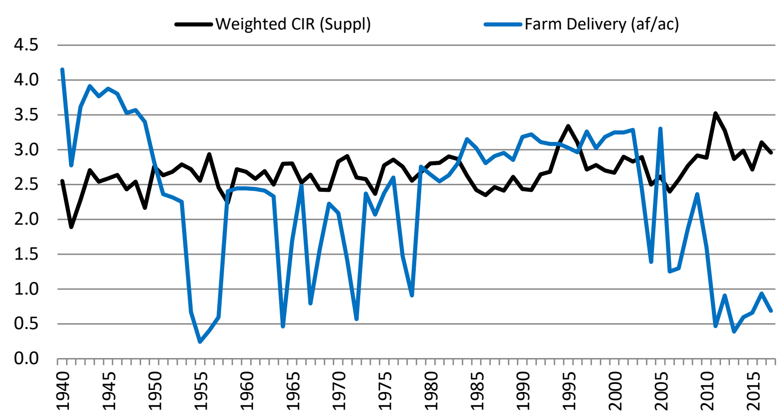
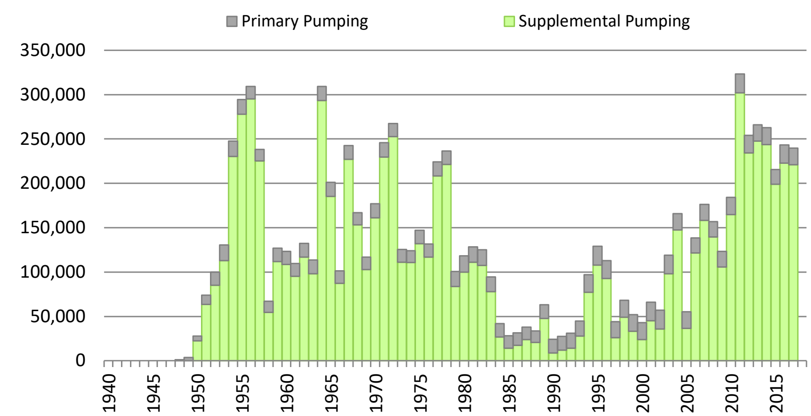
Maximum Application Efficiency and Loss Percentages



Annual Weighted Crop Irrigation Requirement (feet)



Annual Pumping (acre-feet)



Model Version: LRG Model v116 Operational Run 1 - Historical Base Run.

Notes:

(1) Gross canal diversions are the sum of diversions at Percha Dam plus Leasburg Dam plus Mesilla Dam (East and West).
(2) Canal loss calculations occur at top of canal and are not in the surface water budget for Mesilla Texas. However a portion of the canal seepage accrues to the ground water objects for Mesilla TX.
(3) Canal returns to river are flows from the canal to the Rio Grande that are not through a wasteway. These can include EPV carriage water, spill water, and water diverted in excess of demands.
(4) Flows to Texas are flows to Texas from the Eastside and Westside Canal.
(5) Loss percentages are divided by canal diversion.
(6) Crop Irrigation Requirement ("CIR") is the total crop consumptive use (a.k.a. consumptive use of applied water) minus effective precipitation.

Model Version: LRG Model v116 Operational Run 1 - Historical Base Run.

Figure 29-11
Simulated Monthly Charged Diversions of Project Water by EBID and EPCWID
Integrated LRG Model - Historical Base Run (Run 1)
1940 - 2017

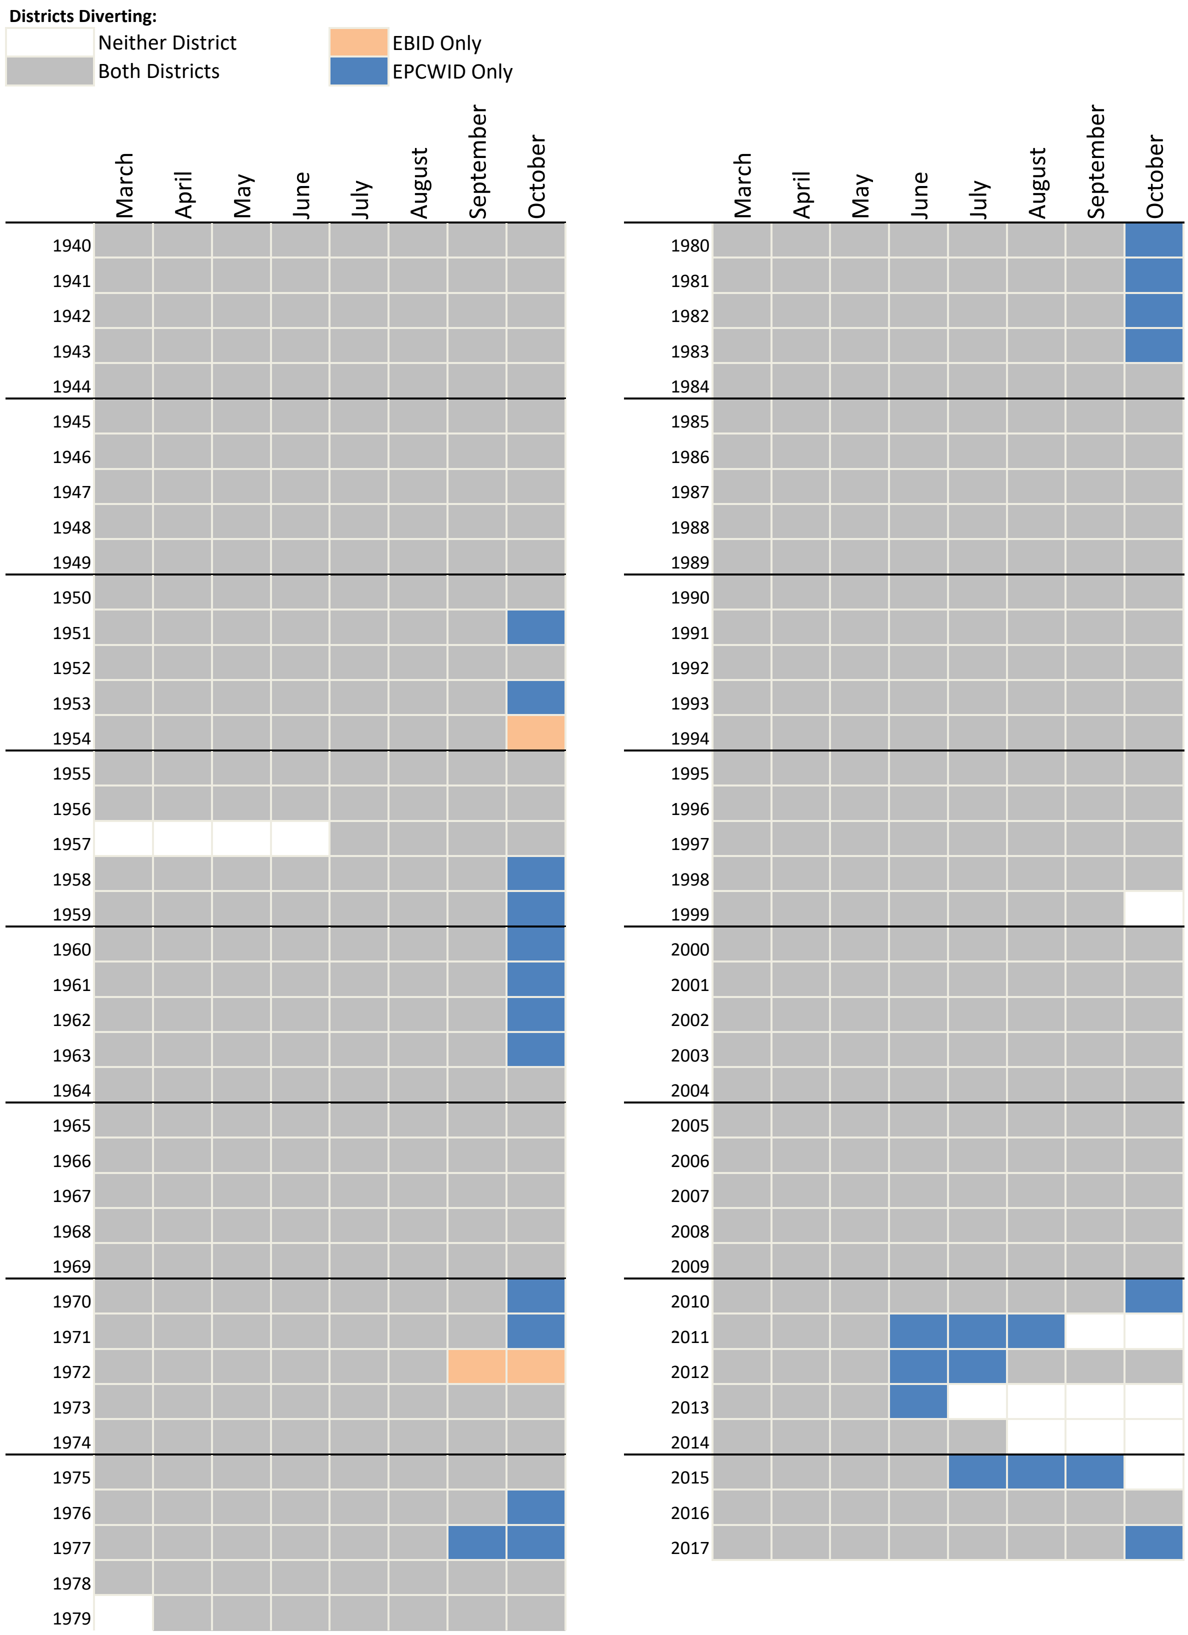

Figure 31-1

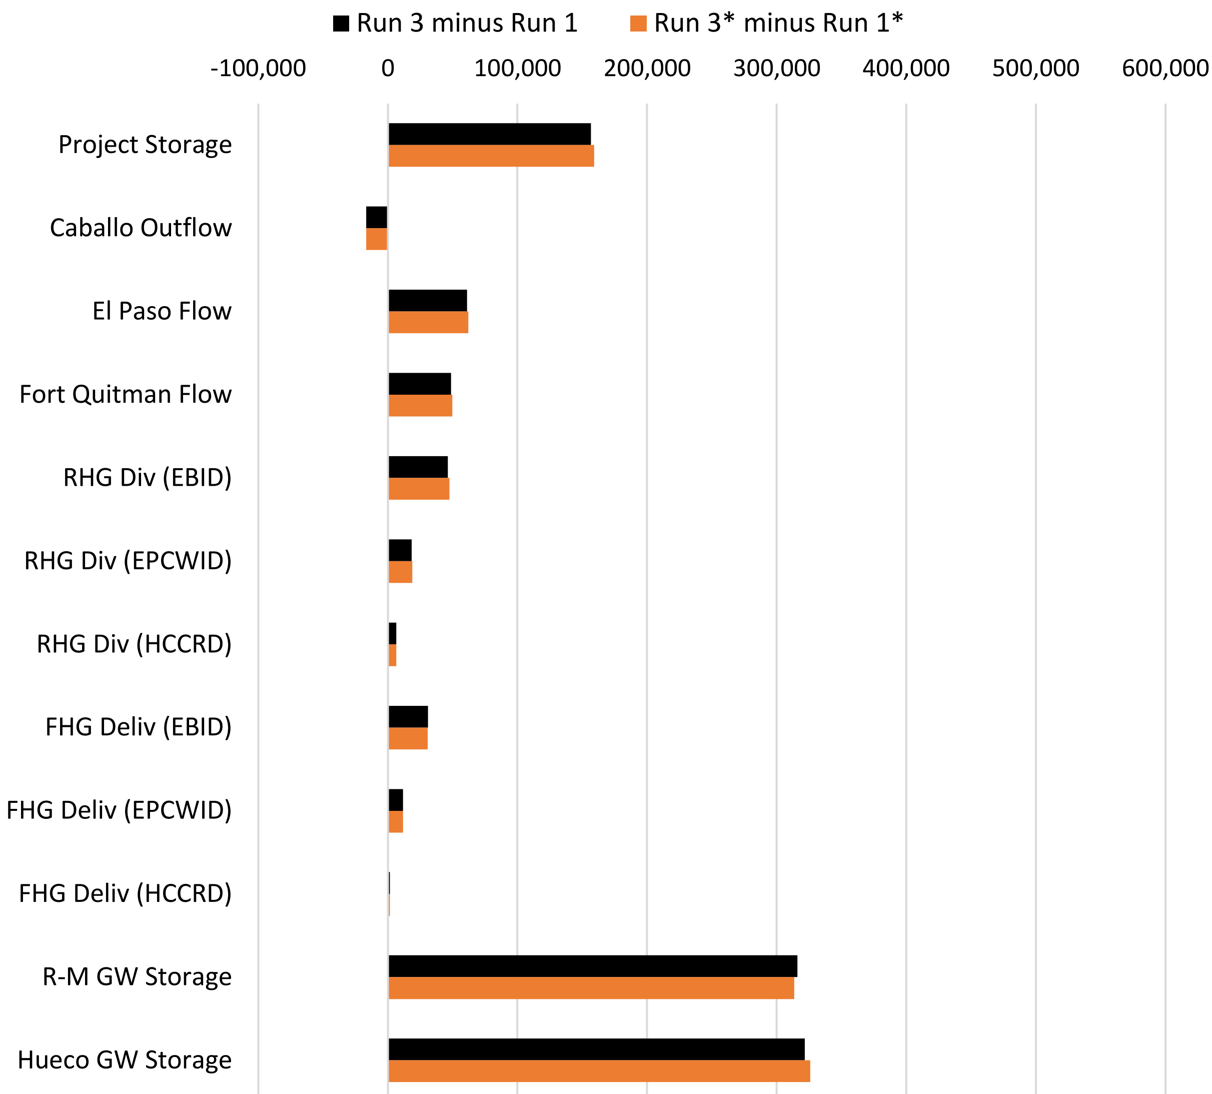
Summary of ILRG Model Sensitivity Analyses
Alluvial Aquifer Hydraulic Conductivity
Average Annual New Mexico Pumping Impacts (Run 3 minus Run 1)
1951 - 2017 (acre-feet)



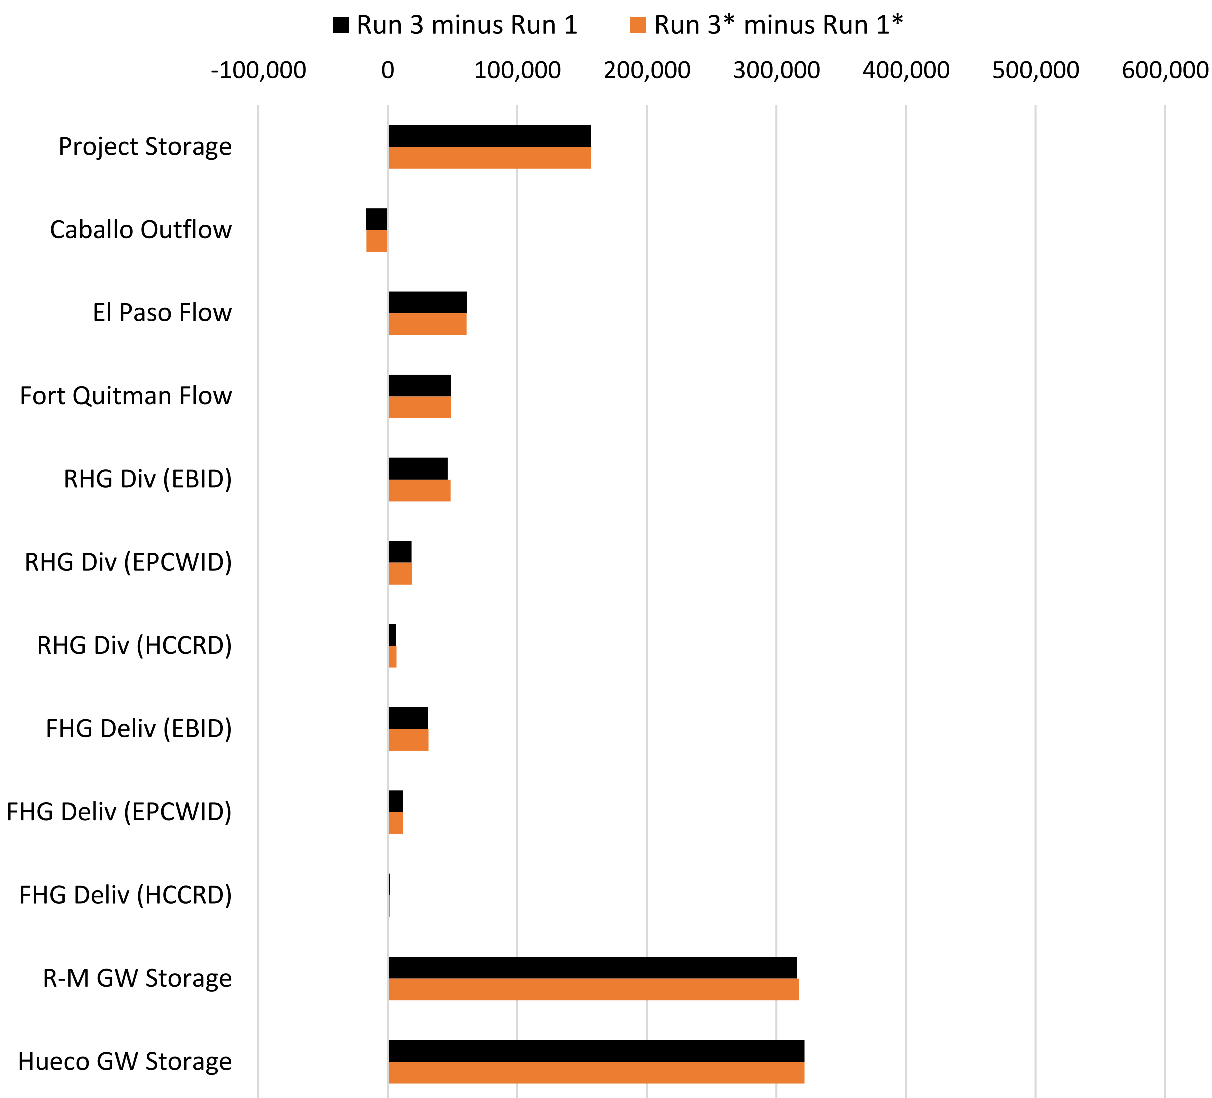
Notes:
Sensitivity Runs (10% Increase in Alluvial Aquifer Hydraulic Conductivity)
Run 1* (Historical Base Run)
Run 3* (NM Pumping Off)

Original Runs
Run 1 (Historical Base Run)
Run 3 (NM Pumping Off)

Changes in storage and flows are annual. Changes in RHG and FHG are irrigation season.

Figure 31-2

Summary of ILRG Model Sensitivity Analyses
River Bed Conductance
Average Annual New Mexico Pumping Impacts (Run 3 minus Run 1)
1951 - 2017 (acre-feet)



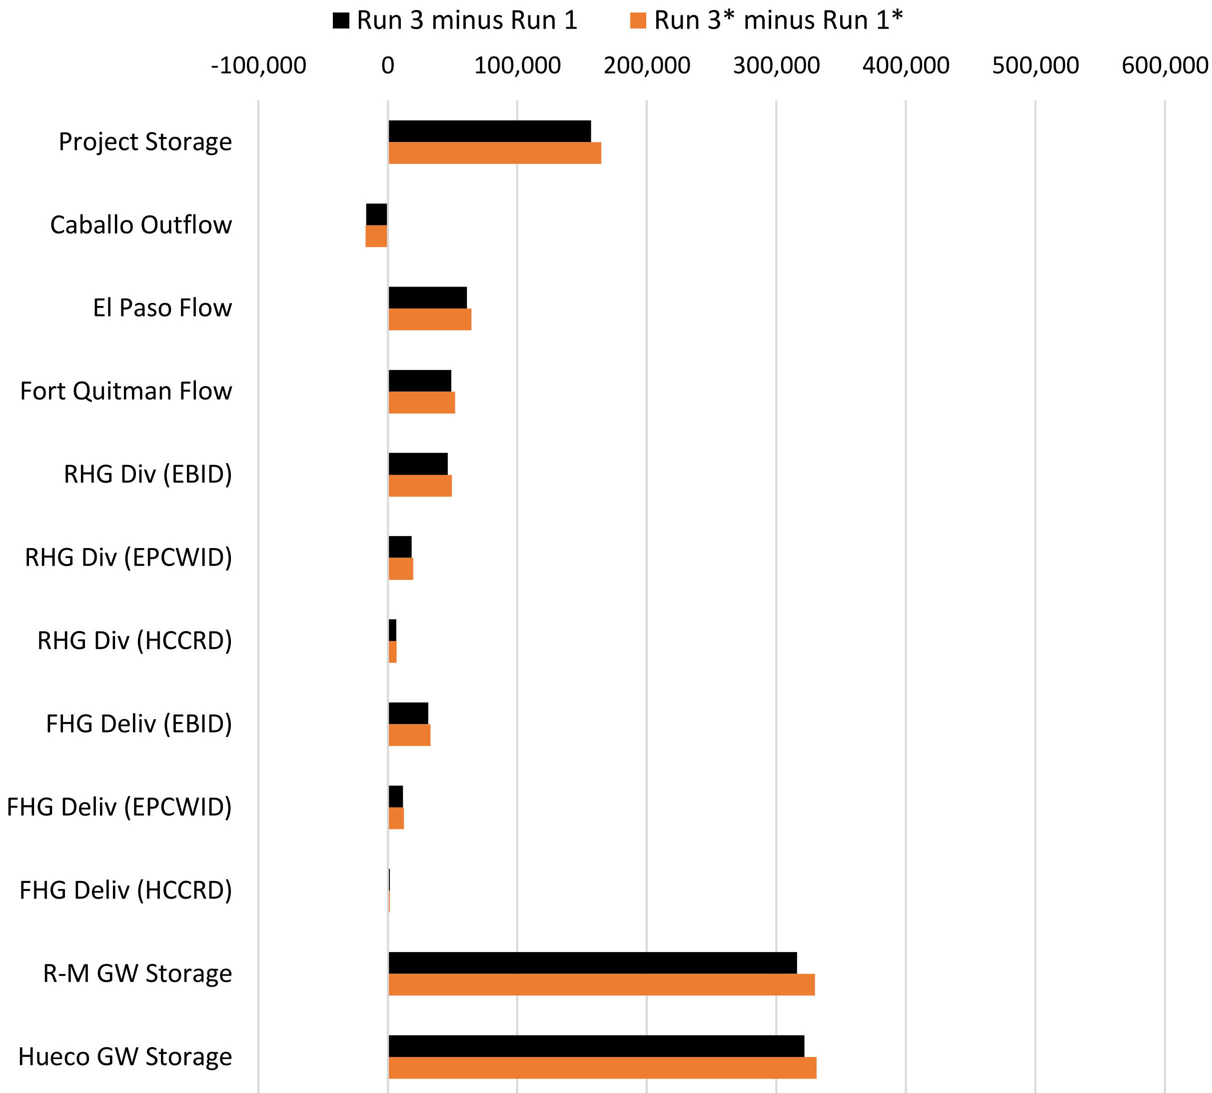
Notes:
Sensitivity Runs (10% Increase in River Bed Conductance)
Run 1* (Historical Base Run)
Run 3* (NM Pumping Off)

Original Runs
Run 1 (Historical Base Run)
Run 3 (NM Pumping Off)

Changes in storage and flows are annual. Changes in RHG and FHG are irrigation season.

Figure 31-3

Summary of ILRG Model Sensitivity Analyses
Canal Bed Conductance
Average Annual New Mexico Pumping Impacts (Run 3 minus Run 1)
1951 - 2017 (acre-feet)



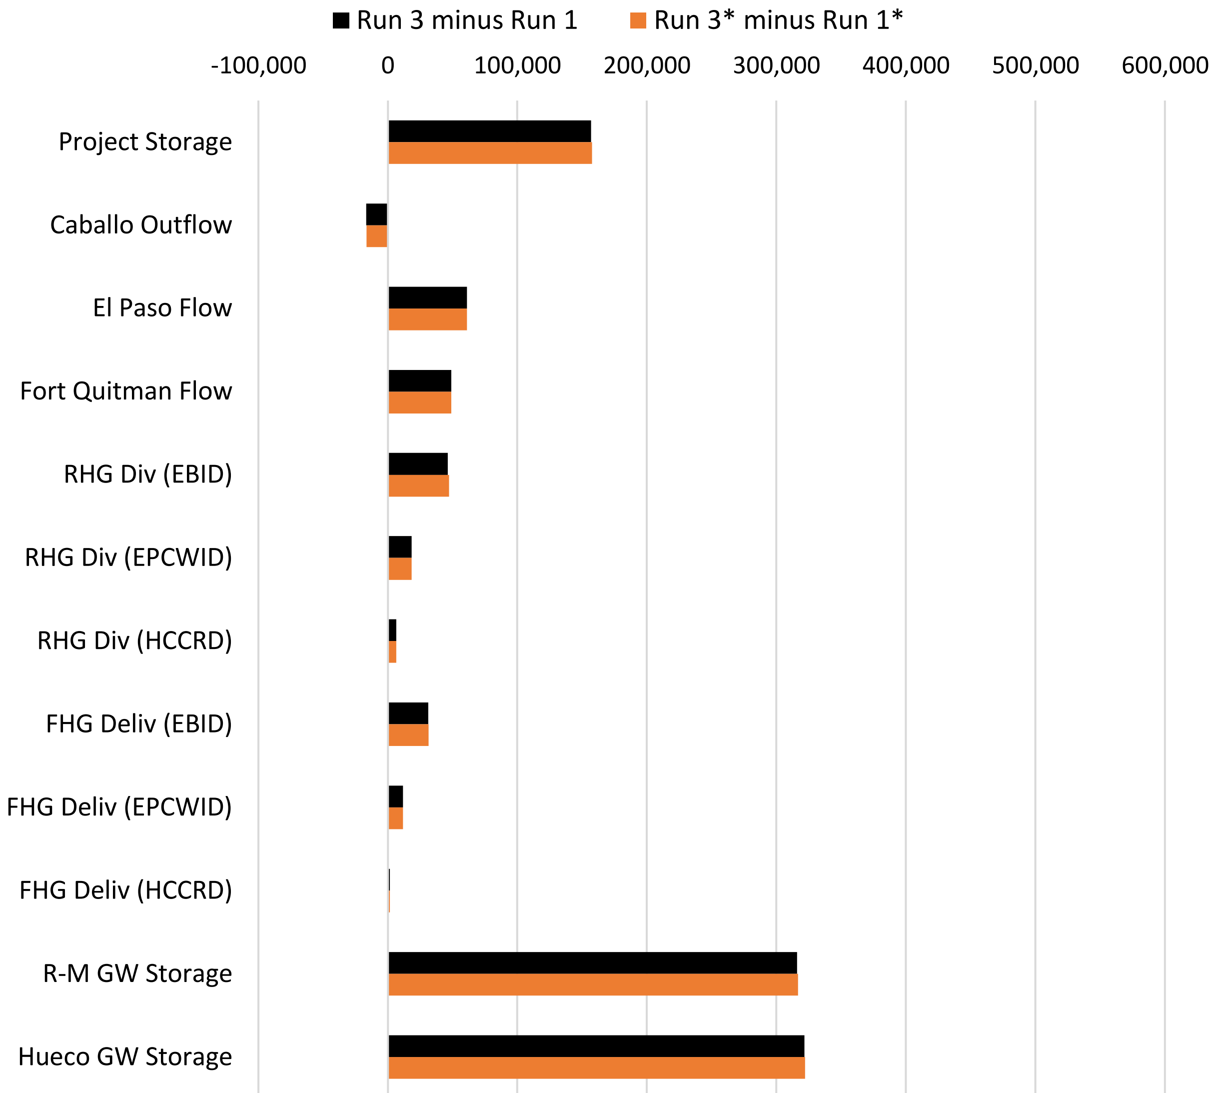
Notes:
Sensitivity Runs (10% Increase in Canal Bed Conductance)
Run 1* (Historical Base Run)
Run 3* (NM Pumping Off)

Original Runs
Run 1 (Historical Base Run)
Run 3 (NM Pumping Off)

Changes in storage and flows are annual. Changes in RHG and FHG are irrigation season.

Figure 31-4

Summary of ILRG Model Sensitivity Analyses
Drain Bed Conductance
Average Annual New Mexico Pumping Impacts (Run 3 minus Run 1)
1951 - 2017 (acre-feet)



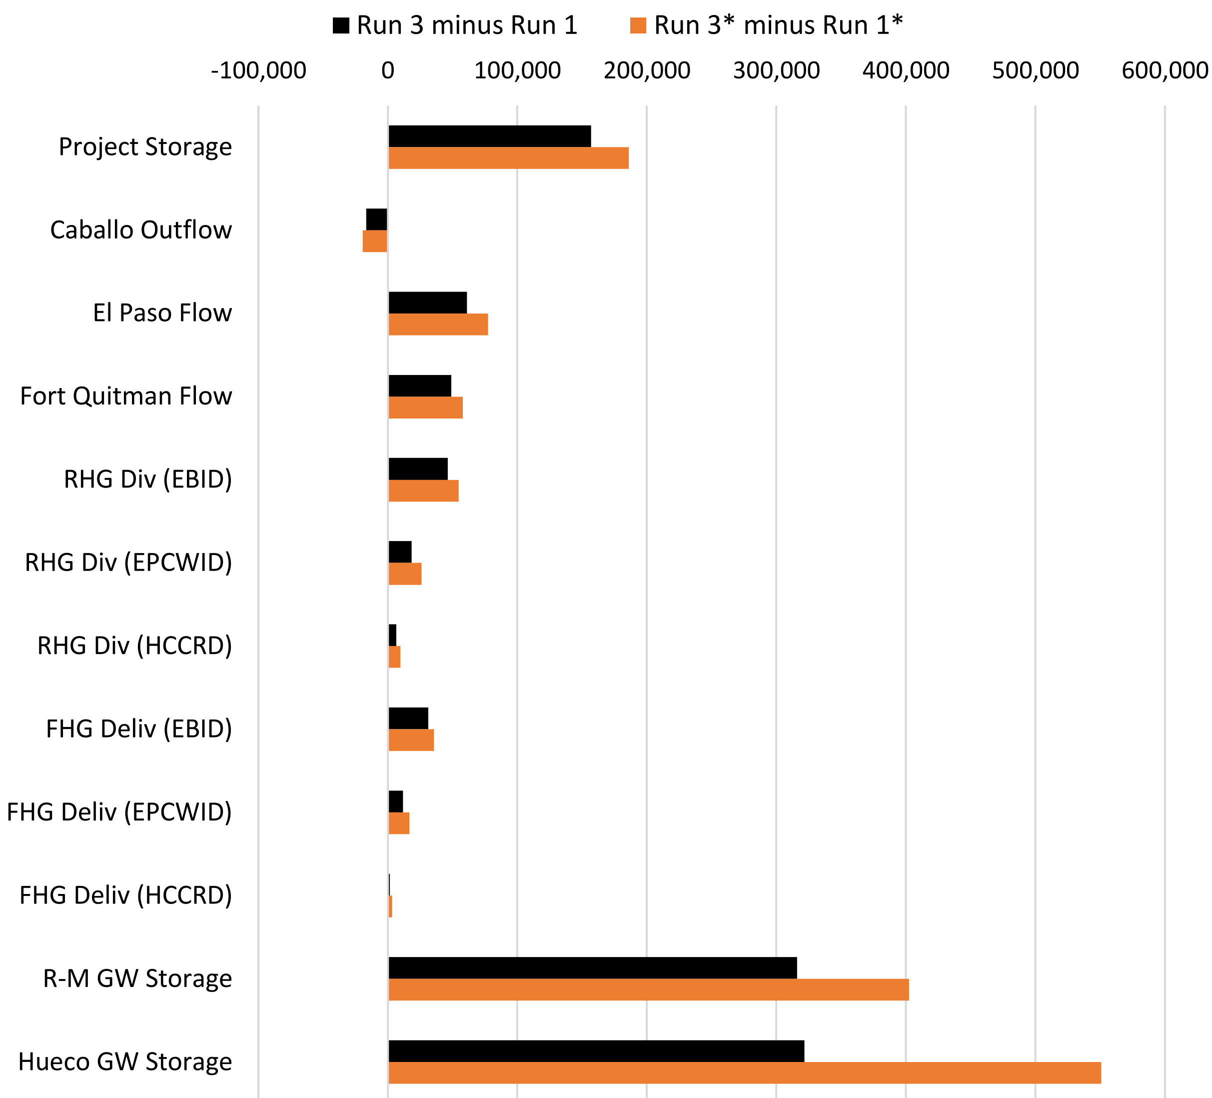
Notes:
Sensitivity Runs (10% Increase in Drain Bed Conductance)
Run 1* (Historical Base Run)
Run 3* (NM Pumping Off)

Original Runs
Run 1 (Historical Base Run)
Run 3 (NM Pumping Off)

Changes in storage and flows are annual. Changes in RHG and FHG are irrigation season.

Figure 31-5

Summary of ILRG Model Sensitivity Analyses
Crop Irrigation Requirement
Average Annual New Mexico Pumping Impacts (Run 3 minus Run 1)
1951 - 2017 (acre-feet)



Notes:

<u>Sensitivity Runs (10% Increase in Crop Irrigation Requirement)</u>
Run 1* (Historical Base Run)
Run 3* (NM Pumping Off)

<u>Original Runs</u>
Run 1 (Historical Base Run)
Run 3 (NM Pumping Off)

Changes in storage and flows are annual. Changes in RHG and FHG are irrigation season.

Notes:

All flow data from SWE SWDataSet.

(1) Sum of Franklin Canal gage, Riverside Canal gage, EPW diversions, WWTP returns, and drains diverted minus Ascarate Wasteway.
(2) 10 % x (1).
(3) Flow data from SWE SWDataset.
(4) Flow data from SWE SWDataset.
(5) Flow data from SWE SWDataset.
(6) Sum of (3) plus (4) plus (5).
(7) Undiverted Fabens Drains is the sum of the River Drain, Middle Drain, Mesa Drain, Cuadrilla Drain, and Fabens Intercepting Drain minus drain water diverted to Tornillo Canal from 1947-1983, and the Fabens Waste Drain from 1984-2017.
(8) Minimum of Hudspeth Feeder Canal flows (4) and Undiverted Fabens Drains (7).
(9) Fabens WWTP discharge into Fabens Waste Channel that can be diverted into Hudspeth Feeder Canal.
(10) Hudspeth Feeder Canal (4) minus Fabens Drains in Hudspeth Feeder Canal (8) minus Fabens WWTP discharge (9).
(11) Sum of Tornillo Canal at Alamo Alto (3) plus Waste in Hudspeth Feeder Canal (10).
(12) Total Waste to Hudspeth (11) in excess of 10 % of EPCWID (El Paso Valley) Supply (2).
(13) Total Waste to Hudspeth (11) / EPCWID (El Paso Valley) Supply (1).

Table 23-1

Spatial Scale of Selected LRG Data
Used in ILRG Model

LRG Data	Portion of Study Period 1940 - 1978	1979 - 2017
River Flows	Point (gage)	
River Headgate Diversions	Point (gage) (1)	
Farm Headgate Deliveries	Valley (2)	District (3)
Canal Loss	Valley (2)	District (3)
Total Waste	Valley (2)	District (3)
Irrigated Area	Valley (2, 4)	District (3, 4)
Cropping Pattern	Valley (2)	District (3)
ET/climate	Basin (5)	
Soils	Basin (5)	
Drain Flows	Point (gage/estimates) (1)	

Notes:

(1) Reported by Canal - Rincon, Leasburg, Eastside (NM and TX), Westside (NM and TX), American, Franklin, Riverside, and Acequia Madre.
(2) Reported by Valley - Rincon, Leasburg, Mesilla (Eastside plus Westside in NM and TX), and El Paso Valley.
(3) Reported by District - EBID, EPCWID, and HCCRD total There are several years after 1979 in which EBID data is separated into Rincon and Mesilla (including Leasburg) totals.
(4) Irrigated area determined by NDVI analysis of satellite imagery in selected years from 1975 - 2017 can be totaled by subarea.
(5) Computed for Rincon-Mesilla basin and Hueco basin.

Table 26-1
Summary of Estimated Data for Surface Water Dataset
Rio Grande Project, Hudspeth County, and Mexico
1903 - 2017

Structure	Start	Period of Record	Missing Data	Method for Estimating Missing Data
Canals - Hueco				
Acequia Madre	Pre-1903	1924 - 1925, 1930 - 1936, 6/1938 - 2006, 2008 - 2017	1903 - 1923, 1926 - 1929, 1937 - 5/1938, 2007	1903 -1923: Used 1924 - 1925 monthly regression with Courchesne gage capped at an estimated diversion capacity (300 cfs) and limited to season of use Mar 1 – Nov 30.
				1926 - 1929 and 1937: Used 1930 - 1936 monthly regression with Courchesne gage capped at an estimated diversion capacity (300 cfs) and limited to season of use Mar 1 – Nov 30.
				1/1938 – 5/1938: Used 1938 annual value less data for period of record in 1938 distributed from Mar - May using Franklin Canal flows.
				2007: Used reported 2007 annual diversion in Rio Grande Compact Commission Report distributed monthly using Franklin Canal diversions.
Franklin Canal	1889	1914 -1916, 1918 - 2017*	1903 – 1913, 1917	1903 -1913 and 1917: Used 1918 - 1938 monthly regression with Courchesne gage capped at an estimated diversion capacity (320 cfs) and limited to season of use Mar 1 – Nov 30. Do not have complete winter diversions in recent years - these winter diversions were not estimated.
Tornillo Canal at Alamo Alto	1947	1947 - 2017*	Various months 1995 – 1996 and 2004 – 2005	Various months 1995 - 1996 and 2004 - 2005: Used 1985 - 1994 monthly regression with Riverside Canal.
Hudspeth Feeder Canal	May-47	1947 - 2017*	2011 - 2012	2011 - 2012: Used 2005 - 2010 monthly regression with Franklin Canal.
Hudspeth Canal (Tornillo End)	1925	1935 - 1955 (ann)	1925 - 1934	1925 - 1934: Estimated flow using water balance (Tornillo Canal heading flow less seepage loss (15%*Tornillo Canal heading) less crop demand for Tornillo acres (CIR*acres/irrigation efficiency) less Tornillo Waste End flows).
				1935 - 1955: Annual data distributed monthly using Tornillo Canal heading flows.

Table 26-1
Summary of Estimated Data for Surface Water Dataset
Rio Grande Project, Hudspeth County, and Mexico
1903 - 2017

Structure	Start	Period of Record	Missing Data	Method for Estimating Missing Data
Canals - Hueco (cont.)				
Juarez River Diversions (below International Dam)	Pre-1903	Annual estimates 1930-1936, 1938-1947, and 1950-1984	1903 - 1929, 1937, 1948-1949, 1985 - 2017	1903 - 1929: Estimated flows based minimum of unmet demand (Farm Budget spreadsheet) limited by estimated flow below International Dam (Courchesne minus Franklin Canal minus Acequia Madre) minus Riverside Canal when applicable.
				1930-1936, 1938-1947, and 1950-1984: Distributed annual estimates monthly using Acequia Madre flows.
				1937: Set equal to 1936 annual estimate.
				1948 - 1949: Estimated flows based on gage differences from Island Station to Fort Quitman.
				1985 - 2017: Did not estimate because there are no gage records.
Wasteways - Hueco				
Franklin Settling Basin WW	1938?	No data		6/1938 – 2/1999: Data provided by Peggy Barroll, NMOSE. Computed using water balance approach (American Canal diversions less Franklin Canal diversions less City of El Paso municipal diversions). Split total computed waste 50/50 between Franklin Settling Basin and Leon St. wasteways. Estimates do not consider transit losses.
Leon St WW	1938?	No data		
Ascarate WW	1916?	1938 - 1954 (ann), 1955 - 2005*	1916 - 1937, 2011 - 2012	1916 - 1937: Used annual regression (1938 - 1949) with Franklin Canal and distributed annual data into monthly values proportional to Franklin Canal flows.
				1938 - 1955: Distributed annual data into monthly values proportional to Franklin Canal flows.
				2011 - 2012: Assumed no Ascarate Wasteway flows until more data become available due to little to zero flows reported since the completion of the American Canal Extension.

Table 26-1
Summary of Estimated Data for Surface Water Dataset
Rio Grande Project, Hudspeth County, and Mexico
1903 - 2017

Structure	Start	Period of Record	Missing Data	Method for Estimating Missing Data
Wasteways - Hueco (cont.)				
Riverside WW#1	1928?	1938 - 1955 (ann combined)**, 1981 - 1984, 1993 - 2017*	Pre-1938, 1956 - 1980,1985 - 1982	1928 – 1937: Used annual regression for combined Riverside WW#1 and WW#2 with Riverside Canal (1938 - 1949) and distributed annual data into monthly values using Riverside Canal diversions. Split between WW#1 and WW#2 using 1981 - 2013 average annual split. Assumed Riverside WW#2 flows do not start until 1930.
				1938 – 1955: Distributed annual data into monthly values proportional to Riverside Canal diversions. Split between WW#1 and WW#2 using 1981 – 2013 average annual split.
Riverside WW#2	1930?			1956 - 1980 and 1985 - 1992: Used annual regression for combined Riverside WW#1 and WW#2 with Riverside Canal (1993 - 2003) and distributed annual data into monthly values using Riverside Canal diversions. Split between WW#1 and WW#2 using 1981 - 2013 average annual split.
Municipal - Hueco				
Northwest WWTP Returns	1987	9/2002 - 2017*	1987 - 8/2002	1987 - 8/2002: Data provided by Nabil Shafike, NMISC - computed using regression with Mesilla EPWU ground water pumping.
Haskell WWTP Returns [(1)]	1923	1936 - 1939, 1940 - 1948**, 1949 - 1959, 1960 - 1975**, 1977 - 2017*	1923 - 1935, 1976, 1/1998 - 9/1998	1923 - 1935: Used annual 1936 - 1940 regression with EPWU pumping. Distributed annual data evenly in each month (divide by 12).
				1976: Used average 1975 and 1977 monthly flow data (i.e., Jan 1976 flow = average Jan 1975 and Jan 1977).
				1/1998 - 9/1998: Used average 1997 and 1999 monthly flow data.
Bustamante WWTP Returns	1991	9/1995 - 2017*	1991 – 8/1995	1991 - 1994: Annual volume derived from reported 1996 influent in gallons per day per capita scaled to Bustamante service area proportion of total City of El Paso population and subtracted Socorro WWTP flows (1991 - 1993). Annual volume divided by 12 to obtain monthly values.
				1/1995 - 8/1995: Annual reported value minus sum of remainder monthly flows (9/1995-12/1995) divided by 8.

Table 26-1
Summary of Estimated Data for Surface Water Dataset
Rio Grande Project, Hudspeth County, and Mexico
1903 - 2017

Structure	Start	Period of Record	Missing Data	Method for Estimating Missing Data
Municipal - Hueco (cont.)				
Socorro WWTP	1967	1967 - 2/1993	1985 - 1988	1967 - 1984: Distributed annual reported volumes evenly into each month (divided by 12). 1985 - 1988: Computed annual volume using linear regression between 1984 and 1989 annual data. Distributed annual estimates evenly into each month (divided by 12). 10/1991: Computed as average 9/1991 and 11/1991 flows.
Juarez Sewage to river	1926?	1940 - 1950 ann	1926 - 1939; 1951 - 2017	1926 - 1939: Data not estimated (not enough information available to estimate). 1940 - 1950: Distributed annual reported estimates evenly into each month (divided by 12). 1951 - 2017: Assume zero (discharge zero by late 1940s).
Juarez Sewage to canals	1926	1950 - 1984	1926 - 1949 and 1985 - 2017	1950 - 1984: Annual reported estimates divided by 12. 1926 - 1949 and 1985 - 2017: Used JMAS pumping provided by MMA multiplied by 49% (same methodology as IBWC 1989 report) minus Juarez Sewage to river (1940 - 1950).
Robertson-Umbenhauer WTP (aka Canal St. WTP)	Nov-43	11/1943 - 2017**	Records for total El Paso WTP prior to 2007	1943 - 1992: Robertson-Umbenhauer WTP equal to total City of El Paso until Jonathan Rogers comes online in 1993.
Jonathan Rogers WTP	1993	1993 - 2017**		1993 - 2006: Split total City of El Paso into each WTP using distribution from available data from 2007 - 2013.
Fabens WWTP	2001	2001 - 2017**	1/2001 - 5/2001, 7/2004, 10/2004	1/2001 - 5/2001 , 7/2004, and 10/2004: Computed using monthly averages from prior and subsequent year.
Municipal - Rincon-Mesilla				
Hatch WWTP	1940	2000 - 2017*	1940 - 1999	1940 - 1999: Computed using regression with population (no pumping data available).
			1/2000 - 9/2000, 11/2005, 10/2013	1/2000 - 9/2000, 11/2005, and 10/2013: Computed using monthly averages from prior and subsequent year.
Las Cruces WWTP	1940	1976 - 2017*	1940 - 3/1976, 5/1979 - 6/1979, 4/1985, 9/1985 - 10/1985	1940 - 3/1976, 5/1979 - 6/1979, 4/1985, and 9/1985 - 10/1985: Computed using regression with pumping.
Anthony NM WWTP	1989	2002 - 2017*	1989 - 1995	1989 - 1995: Computed using regression with pumping.

Table 26-1
Summary of Estimated Data for Surface Water Dataset
Rio Grande Project, Hudspeth County, and Mexico
1903 - 2017

Structure	Start	Period of Record	Missing Data	Method for Estimating Missing Data
Municipal - Rincon-Mesilla (cont.)

Performance Evaluation Criteria for Selected Statistics from Moriasi (2015)

Rating	NSE	R^2	d	PBIAS
Very Good	0.80 < NSE	0.85 < R^2	0.90 < d	PBIAS < +/- 5
Good	0.70 < NSE ≤ 0.80	0.75 < R^2 ≤ 0.85	0.85 < d ≤ 0.90	+/- 5 ≤ PBIAS < +/-10
Satisfactory	0.50 < NSE ≤ 0.70	0.60 < R^2 ≤ 0.75	0.75 < d ≤ 0.85	+/- 10 ≤ PBIAS < +/-15
Not Satisfactory	0.00 < NSE ≤ 0.50	0.18 < R^2 ≤ 0.60	0.60 < d ≤ 0.75	+/- 15 ≤ PBIAS < +/-30
Unacceptable	NSE ≤ 0.00	R^2 ≤ 0.18	d ≤ 0.60	+/- 30 ≤ PBIAS

Notes:

(1) Annual statistics denoted with (A), irrigation season statistics denoted with (I)
(2) Log NSE computed using modeled and observed flows adjusted by adding 1,000 AF to streamflows and 100 AF to diversions, farm headgate deliveries, pumping, and drains flows
(3) Total Hudspeth Supply includes Tornillo Drain, Tornillo Canal at Alamo Alto, and Hudspeth Feeder Canal
(4) Rincon Valley Drains statistics are computed for 1951-2002 due to limited data available after 2002
(5) Mesilla Valley Drains are computed for 1951-2013 due to limited data available after 2013
(6) El Paso Valley Drains include the Fabens Waste Drain and the Tornillo Drain

Table 30-1

ILRG Model

Run No.	Name	Compare To Run	Notes
0	Historical Calibration Run		
1	Historical Base Run (All Pumping On)	0	
2	All Pumping Off	1	(1)
3	NM Pumping Off	1	(1)
4	TX Pumping Off	1	(1,2)
5	MX Pumping Off	1	(1)
6	R-M Pumping Off	1	(1,3)
7	TX Mesilla Pumping Off	1	(1)
8	TX Non-Irrigation Pumping Off	1	(1)
9	NM Non-Irrigation Pumping Off	1	(1)
10	MX Non-Irrigation Pumping Off	1	(1)
11	D1/D2 Allocation (All Pumping On)	1	(4)
12	D3+Carryover Allocation (All Pumping On)	11	(4)
13	Reduced Waste	1	

Notes:
(1) Corresponding WWTP returns and urban deep percolation returns are also turned off (no UDP simulated in Mexico).
(2) Including Texas Mesilla (EPCWID Mesilla and EPW Canutillo Wellfield).
(3) Including Texas Mesilla and Mexico Conejos-Medanos.
(4) Project allocation procedure simulated for 1950-2017.

Table 30-2

List of Additional Model Runs
ILRG Model

Run No.	Name	Compare To Run	Notes
14	All Hueco Pumping Off	1	
14a	TX Hueco Pumping Off	1	
14b	MX Hueco Pumping Off	1	
14c	Texas WWTP Discharges Off	1	
14d	TX Hueco Pumping Off (Returns Left On)	1	
15	Early EPCWID Ops (WWTP & Fabens Drains)	1	(1)
15a	Early EPCWID Ops (WWTP)	1	(2)
15b	Early EPCWID Ops (Fabens Drains)	1	(3)
15c	Early EPCWID Ops (TX Hueco Pumping Off)	15	(1)
16	Conj Use 1: Hist All Acres D1/D2 (Hist M&I)	1	(1,4,9)
16a	Conj Use 1a: Hist All Acres D1/D2 (1978 M&I)	1	(1,5,9)
17	Conj Use 2: Hist Proj Acres (Hist M&I)	1	(1,6,9)
17a	Conj Use 2a: Hist Proj Acres (Pre-Comp M&I)	1	(1,7,9)
18	Conj Use 3: Auth Proj Acres (Pre-Comp M&I)	1	(1,8,9)

Notes:

(1) EPCWID increased use of Fabens drain flows; charge EPCWID for use of EPW WWTP returns and drain flows; No ACE or Haskell credits.
(2) Charge EPCWID for use of EPW WWTP returns; no ACE or Haskell credits.
(3) EPCWID increased use of Fabens drain flows and charge for drain flow use.
(4) Conjunctive use pumping on historical Project acres; pumping on NM GW only acres; D1/D2 allocation and accounting for 1951-2017; limit 10-year average irrigation pumping to 1951-1978 average; historical M&I pumping.
(5) Same as (4) except limit M&I pumping to 1951-1978 max.
(6) Conjunctive use pumping on historical Project acres; no pumping on NM GW only acres; D1/D2 allocation and accounting for 1951-2017; no limit on irrigation pumping; historical M&I pumping.
(7) Same as (6) except limit M&I pumping to pre-compact amounts.
(8) Conjunctive use pumping on authorized acres; irrigation of authorized Project acres every year 1940-2017 (EBID-88,000 ac, EPCWID-67,000 ac); irrigation of 17,750 acres (max) for HCCRD1 every year; irrigation of historical Juarez acres; no pumping on NM GW only acres; limit M&I pumping to pre-compact amounts, no EPW use of Project water.
(9) Turn off Las Cruces WWTP discharge and urban deep percolation that originates from pumping of Jornada wells.

Table 30-3

Average Annual Change in Simulated Flows
Rincon-Mesilla Pumping Off
1951-2016 (AF)

	Change in Model Output	(1) ILRG Model (Annual)	(2) ILRG Model (Irrigation Season)	(3) Texas Model (Hutchison)	(4) Texas Model (Moran)

R-M GW Storage	316,097	-2,557	-1%	1,236	0%	13,836	4%	531	0%	86,288	27%
Hueco GW Storage	321,784	4,080	1%	-100	0%	9,168	3%	364	0%	229,186	71%

Notes:

(1) Change in Run 3 minus Run 1 differences for a 10% increase in selected input parameters/data.
Run 3 (No NM Pumping) minus Run 1 (Historical Base Run)

(2) Percent change calculated using the following formula:

$$\frac{(Run\ 3^{*}\ minus\ Run\ 1^{*})\ minus\ (Run\ 3\ minus\ Run\ 1)}{(Run\ 3\ minus\ Run\ 1)}$$

(3) Changes in storage and flows are annual. Changes in RHG and FHG are irrigation season.

Appendix 17

Errata
Rebuttal Expert Report
Gregory K. Sullivan, P.E.
and
Heidi M. Welsh
Second Edition

Report Text

P. vi, Bullet 6, Line 1:	"River Conductance" should read "River Bed Conductance"
P. vi, Bullet 7, Line 1:	"Canal Conductance" should read "Canal Bed Conductance"
P. vi, Bullet 8, Line 1:	"Drain Conductance" should read "Drain Bed Conductance"
P. 1, Bullet 6, added:	Also on July 15, 2020, the New Mexico experts submitted revised or second editions of their opening expert reports.
P. 2, Paragraph 4, added:	A second edition of the SWE Rebuttal Report was prepared to describe corrections and improvements that have been made to the ILRG Model, to report the results of the model re-tuning, and to present the results of the updated Base Run (Run 1) and alternative scenario runs (Runs 2 – 18). This second edition report also corrects typographical errors in the original SWE Rebuttal Report. A new Appendix 17 is attached that contains an errata list for Sections 17-29 and 31, a redline depiction of the changes to Section 30, and a list of the figures, tables, and appendices revised for this second edition.
P. 7, Paragraph 6, Line 4:	"ILRG reflect" should read "ILRG Model reflect"
P. 8, Paragraph 5, Line 6:	"evaluated" should read "evaluation"
P. 9, Paragraph 5, Line 6:	"impacts being caused" should read "impacts caused"
P. 13, Paragraph 2, Line 1:	"(v111)" should read "(v116)"
P. 14, Paragraph 6, Line 8:	"Run 14c)" should read "(Run 14c)"

P. 26, Table for Run 14c, Line 3:	"-3,500" should read "-8,200", and "-10,600" should read "-11,700"
P. 32, Paragraph 8, Line 3:	"and discharges" should read "discharges"
P. 32, Paragraph 8, Line 4:	"discharges" should read "and discharges"
P. 33, Paragraph 2, Line 4:	"Figure 19-16" should read "Figure 19-13"
P. 49, Paragraph 1, Line 3:	"significance" should read "significant"
P. 54, Paragraph 3, Line 6:	"variable. Rio Grande inflows to Project storage are supply is managed" should read "variable Rio Grande inflows to Project storage are managed"
P. 55, Paragraph 1, Line 6:	"no" should read "not"
P. 60, Paragraph 1, Line 2:	"irrigation from" should read "irrigation season from"

P. 70, Paragraph 5, Line 6:	"15%" should read "16%"
P. 70, Paragraph 5, Line 6:	"(satisfactory to very good)" should read "(not satisfactory to very good)"
P. 71, Paragraph 2, Line 3:	"relative MAE" should read "PMAE"
P. 71, Paragraph 2, Line 4:	"34%" should read "36%"
P. 71, Paragraph 4, Line 4:	"three" should read "one"
P. 71, Paragraph 5:	"Of the three NSE values that are less than 0.50, two are for HCCRD – FHG deliveries and the related supplemental pumping to meet unmet demands. The simulated Total HCCRD Supply is simulated well with an NSE of 0.89. The less impressive simulation of HCCRD FHG deliveries is hampered by the general lack of information disclosed by Texas regarding how HCCRD operates. The third NSE value less than 0.50 is for the aggregated Rincon Valley drain flows which on average after 1950 flowed less than 15,000 AF/y." should read "The only NSE value less than 0.50 is for the aggregated Rincon Valley drain flows which on average after 1950 flowed less than 15,000 AF/y."
P. 72, Paragraph 7, Line 2:	"0.94" should read "0.93"
P. 73, Paragraph 3, Line 7:	"0.94" should read "0.93"
P. 75, Paragraph 2, Line 6:	"-1.6%" should read "-1.8%"
P. 82, Paragraph 5, Line 4:	"14,900" should read "17,800"
P. 82, Paragraph 5, Line 5:	"64,100" should read "54,600"
P. 86, Paragraph 5, Line 3:	"years, but not all, these impacts are particularly offset" should read "years some, but not all, of these impacts are offset"
P. 90, Paragraph 5, Line 1:	"reoperation" should read "redistribution"
P. 93, Table, Heading:	"Original (v 106) and Updated (v 111)" should read "Original (v106) and Updated (v116)"
P. 93, Table, Line 1:	"(v111)" should read "(v116)"
P. 93, Table, Line 3:	" -0.3" should read "-0.9"
P. 93, Table, Line 4:	"-1.4" should read "-0.7"
P. 93, Table, Line 7:	"-2.3" should read "-3.0"
P. 93, Table, Line 8:	"1.6" should read "2.3"
P. 93, Table, Line 9:	"-0.5" should read "-0.6"
P. 93, Paragraph 4, Line 2:	"44,700" should read "47,600"
P. 93, Paragraph 4, Line 2:	"54,700" should read "58,100"
P. 95, Paragraph 2, Line 4:	"average overprediction or underprediction" should read "average underprediction"

P. 95, Paragraph 2, Line 5:	“10%” should read “5%”
P. 95, Paragraph 2, Line 6:	“Good” should read “Very Good”
P. 102, Paragraph 2, Line 1:	“(v111)” should read “(v116)”
P. 104, Bullet 7, added:	River Headgate Demand - Rearrange the equation that computes the river headgate demands so that the tuning factor is only applied to the crop, soil moisture, and EPW demands, and not to the conveyance losses and EPCWID use of WWTP discharges and drain flows.
P. 104, Bullet 8, added:	EPCWID Allocation Limit - Adjust the rule that limits EPCWID diversions when the EPCWID has less remaining allocation than demand.
P. 104, Bullet 9, added:	EPCWID FHG Deliveries – Add river seepage as an independent term in the equation that computes the EPCWID farm headgate deliveries.
P. 104, Bullet 10, added:	ACE Credit – Revise the rule that computes the ACE Credit to use the equation that has historically been most frequently used in the Project accounting.
P. 105, Bullet 5, added:	Rincon and Mesilla Valley Canal Capacities – Reduce the simulated capacity of the Rincon, Leasburg, Eastside, and Westside canals to limit the simulated maximum monthly diversions consistent with historical diversion records.
P. 111, Bullet 4, Line 2:	“with a slight underprediction trend throughout the “should read “with some underprediction late in the”
P. 115 to 135, Section 30:	Section 30 changes are documented in the redline version of the text for this section that is included in this appendix as Attachment 17-A.
P. 137, Bullet 1, Line 3:	“(2% or less).” should read “(4% or less)
P. 137, Bullet 3, Line 4:	“(4% - 8%)” should read “(0% - 7%)”
P. 137, Bullet 3, Line 5:	“(3 - 4%)” should read “(3% - 5%)”
P. 137, Bullet 3, Line 6:	“(4% - 6%)” should read “(3% - 6%)”
P. 137, Bullet 5, Line 1	“had” should read “has”
P. 138, Paragraph 1, Line 2	“17% - 27%” should read “15% - 43%”

Corrections to Run Summaries and Run Comparisons in Appendices 30B – 30AA

Column BB in the "ModelRun" tab in each run summary spreadsheet was corrected to reflect the total Rio Grande Project Storage (Elephant Butte Reservoir + Caballo Reservoir). This change affects the reservoir storage data presented in Figure 29-1. In addition, this change affects the reservoir storage data presented in the upper table on page 3, the upper graph on page 6, the upper left graph on page 11, and the graphs on page 19 for each run comparison included in Appendices 30B – 30AA.

Columns E, S, and AI on the "Diff Charts" tab in each run comparison spreadsheet were corrected to reflect annual Caballo Reservoir release data. This change affects the lower right inset graph for Caballo Reservoir Outflows on page 6 of each run comparison included in Appendices 30B – 30AA.

ATTACHMENT 17A

30.0 ALTERNATIVE RUNS OF ILRG MODEL

The updated ILRG Model (v1116) was used to re-run the no-pumping scenarios and operations scenarios that were presented in the SWE Report (Runs 2 – 13). A list of the original model runs is provided in **Table 30-1**.

In addition to re-running the original 13 scenarios, the updated ILRG Model was used to simulate additional no-pumping scenarios and operations scenarios. These included Run 14 and several variants that simulate the effects of pumping in the Hueco and Run 15 and several variants that simulate early EPCWID operations prior to changes in water use practices. In addition, five other scenarios were simulated (Runs 16, 16a, 17, 17a, and 18) to analyze conjunctive use of surface water and ground water. These conjunctive use scenarios are based on either a D1/D2 level of supplemental pumping or a supplemental pumping level up to the crop demands on the authorized Project acres, and were developed in consultation with representatives and legal counsel for New Mexico. A list of the additional model runs is provided in **Table 30-2**. Additional specifications for the model runs are provided in **Appendix 30-A** including details for Runs 15-18 and details for the WWTP discharges and urban deep percolation returns that are turned off or reduced in certain of the alternative scenarios.

The results from the re-running of the original scenarios and simulation of the new scenarios are presented in a consistent format in the tables and graphs in **Appendix 30**. These include tabular and graphical results similar to those presented in the SWE Report as well as several additional tables and graphs. Unless otherwise noted, all of the results presented in **Appendix 30** are comparisons between an alternative scenario and the Historical Base Run (Run 1). There are 22 pages of tables and graphs included in the run comparisons for each scenario. An overview of the format and content of each of these tables and graphs follows:

- Cover Page (p. 1) – Selected input specifications for the two runs being compared.

- Comparison of ILRG Model Runs (p. 2-3) – This two-page table provides a high-level overview of how the ILRG Model distributes the change in inputs (e.g., change in pumping stress or change in operating rules) into changes in model outputs. The first five rows of values are the average annual pumping stresses in each run, which consist of the irrigation pumping that is on in Run 1 and off in the alternative run, and the total non-irrigation pumping and non-irrigation pumping return flows (WWTP discharges and urban deep percolation). The Total Stress is computed as the sum of the irrigation and non-irrigation pumping less the non-irrigation returns flows. The third column of numbers shows the difference in stress between the two runs being compared. The remainder of the table reports the annual averages for selected ILRG Model outputs and the differences in outputs between the two runs. The fourth and fifth columns of numbers express the average annual output differences as percentages of the change in Total Stress and as percentages of the Base Run values. For the alternative runs that simulate differences in operating rules (i.e. Runs 11-13, 15-18), there are no rows in the table listing the stresses, nor is there a column listing the % Change Stress.

- Annual Differences in ILRG Model Outputs (p. 4-5) – This two-page table lists the differences in model outputs for selected model outputs. These include the differences in irrigation season and annual net RHG Diversions and FHG Deliveries, and differences in annual river flows at the Caballo outlet, El Paso, and Fort Quitman. Net RHG Diversions are defined as the simulated gross diversions less the historical El Paso carriage water that was delivered through the Rincon and Mesilla Valley canals and less the simulated flood control releases that were run through the canals in spill years. Reporting of differences in net RHG Diversions in the model results represents a change from the reporting of differences in gross RHG diversions that were presented in model results described in the SWE Report.

- Simulated Differences in ILRG Model Outputs (p. 6-9) – These four pages of graphs and tables show differences in model outputs expressed as either annual or irrigation season totals. There is a bar chart with the yearly differences in model output, an inset line chart showing the annual outputs that are differenced in the bar chart, and a table summarizing the yearly average differences (annual or irrigation season totals). The differences in net RHG diversions and FHG deliveries are shown in line graphs rather than bar charts.

- Annual Allocation and Charges (p. 10) – This chart summarizes for the two compared runs the simulated annual allocation and delivery charges for EBID and EPCWID, as well as the simulated annual Diversion Ratio computed as the sum of the annual diversion charges for EBID, EPCWID, and Mexico divided by the annual Caballo Reservoir releases.

- Annual Summary of Project Storage and Rio Grande Flows (p. 11) – This chart summarizes for the two compared runs the total year-end project storage in Elephant Butte and Caballo Reservoirs and the annual Rio Grande flow at the Caballo Reservoir outlet, at El Paso, and at Fort Quitman.

- Irrigation Season Summary of Irrigation Operations (p. 12-14) – These three pages of charts summarize for the two compared runs the net RHG diversions, FHG deliveries, irrigation pumping, and RHG diversions minus FHG deliveries (conveyance losses). There are separate pages for EBID, EPCWID, and HCCRD.

- Cumulative Change in Ground Water Storage (p. 15) – This chart summarizes for the two compared runs the cumulative year-end change in ground water storage in the alluvial and non-alluvial aquifers in the Rincon and Mesilla valleys and in the Hueco.

- Monthly Net RHG Diversions (p. 16-18) – These three pages of charts show for the two compared runs the simulated monthly net RHG diversions. There are charts showing the total EBID diversions, total EPCWID diversion, and the total flow to HCCRD.

- End of Month Reservoir Storage (Elephant Butte + Caballo) (p. 19) – This chart shows for the two compared runs the combined end-of-month Project storage in Elephant Butte and Caballo Reservoirs. This doesn't include storage of non-Project water.

- Monthly Rio Grande Flows (p. 20-22) – These three pages of charts show for the two compared runs the simulated monthly Rio Grande flows at the Caballo Reservoir outlet, at El Paso, and at Fort Quitman.

Narrative summaries of the ILRG Model simulations of alternative scenarios are provided below to highlight and explain some of the more significant results shown in the tabular and graphical summaries presented in **Appendix 30**. The tables in **Appendix 30** include annual and irrigation season differences in model outputs for all run comparisons. Averages are computed for the following noteworthy ranges of years:

1951-2017: Period with irrigation pumping development commencing with the beginning of the D1/D2 data period (57/43 allocation until 2006).

1951-1978: D1/D2 data period (57/43 allocation).

1979-2005: Post D1/D2 data period prior to the 2008 OA allocation and accounting that commenced in 2006 (57/43 allocation).

2006-2017: Period when the 2008 OA allocation and accounting was in effect (D3 allocation for 2006 and 2007, D3 allocation plus carryover for 2008-2017).

1985-2017: Period for which alleged damages were computed by Texas (1985-2016) plus the last year of the study period (2017).

1985-2005: Portion of the Texas damages period prior to commencement of the 2008 OA allocation and accounting.

Averages for other portions of the study periods can be computed from the data in the run comparison spreadsheets that are being disclosed with this report.

30.1 All Pumping Off (Run 2)

In Run 2, all irrigation and non-irrigation pumping in the study area is turned off, and all non-irrigation returns, including WWTP discharges and urban deep percolation returns, are also turned off. The changes in irrigation returns that result from turning off the irrigation pumping are simulated by the farm budget processes included in the model.

The ILRG Model re-operates the Project and all of the simulated irrigation systems in the absence of pumping. Turning off pumping increases drain flows and reduces river seepage in most years. During full allocation years, this results in water accumulating in storage as less water needs to be released to meet demands. Accumulating water in storage increases allocations and Caballo Reservoir releases in subsequent dry years (e.g., several years in the 1960s, 1970s, and 2000s). Spills are also larger due to the accumulated water in storage.

The increased allocations result in increased diversions and FHG deliveries to EBID in dry years between 1950 and 1978. During the full allocation years from 1979 – 2002, there is little change in EBID diversions, however FHG deliveries increase modestly due to reductions in the simulated canal conveyance losses in the no-pumping run that allowed more of the water that is diverted to be delivered to the farms. When dry conditions return, EBID diversions and FHG deliveries increase again in 2003 and 2004. EBID diversions increase substantially beginning in 2006 due to the effects that pumping has when the 2008 OA is in effect. As is discussed in Barroll (2019), EBID's allocation under the 2008 OA is sensitive to the diversion ratio. When pumping is turned off, the diversion ratio increases resulting in increased allocations and increased deliveries to EBID. On average from 2006 – 2017, EBID's diversions increase by 148,700~~145,400~~ AF and FHG deliveries increase by 92,700~~93,200~~ AF.

The increase in Project water allocations also results in increased diversions and FHG deliveries to EPCWID in many dry years in the 1950s – 1970s. There are also modest increases in EPCWID diversions during many full allocation years in the 1980s and 1990s because the reduction in EPW WWTP discharges to EPCWID canals results in EPCWID requiring more reservoir releases to meet its demands. Increases in deliveries also occur in several dry years in the 2000s – 2010s although the increases are not near as large under the 2008 OA after 2005 as they are for EBID.

Turning off pumping and the resulting effects on Project operations and deliveries results in increased Rio Grande at El Paso flow in most years averaging 79,000~~80,500~~ AF annually during 1951 – 2017. Of this amount, an average of only 33,100~~38,900~~ AF occurs during the irrigation season (Mar-Oct) and the remaining 45,900~~41,600~~ AF occurs during the non-irrigation season (Nov-Feb) or during reservoirs spill. During the 1985-2005 period, the increase in irrigation season flows, excluding spills, averages 15,700~~28,600~~ AF. A portion of the increase is attributable to turning off New Mexico pumping and a portion is due to turning off Texas pumping. Cessation of pumping also produces substantial increases in flow at Fort Quitman averaging 100,300~~102,900~~ AF annually during 1951-2017.

30.2 NM Pumping Off (Run 3)

In Run 3, all irrigation pumping and all non-irrigation pumping and returns in New Mexico is turned off. This includes all EBID supplemental irrigation pumping, all primary irrigation pumping in the Rincon Valley and Mesilla Valley, and all non-irrigation pumping and associated WWTP discharges and deep percolation returns in New Mexico.

Many of the simulated effects of turning off New Mexico pumping are similar to but smaller than the effects of turning off all pumping in Run 2. There is a similar pattern of accumulations in Project storage that are released in dry years when the simulated Project allocations increase~~d~~. The accumulated storage again leads to larger spills.

EBID diversions increase by an average of 46,300~~46,600~~ AF during 1951-2017, while FHG deliveries increase by an average of 31,200~~33,700~~ AF. When the 2008 OA is in effect during 2006-2017, turning off New Mexico pumping increases EBID diversions by an average of 137,500~~134,200~~ AF, and FHG deliveries increase by an average of 83,900~~84,100~~ AF.

The impacts of New Mexico pumping on EPCWID supply are less than the impacts on EBID. From 1951 – 2017, EPCWID irrigation season diversions increase by an average of 18,500~~19,200~~ AF and FHG deliveries increase by an average of 11,700~~11,600~~ AF. After 1984 when Texas is claiming damages, New Mexico pumping impacts EPCWID irrigation season diversions by an average of 17,200~~13,200~~ AF and irrigation season FHG deliveries by an average of 9,700~~7,400~~ AF (1985-2017). During 1985-2005, prior to implementation of the 2008 OA, EP~~W~~CWID irrigation season diversions increase by an average of 10,900~~7,200~~ AF and irrigation season FHG deliveries increase by an average of 5,100~~3,200~~ AF.

Simulated flows in the Rio Grande at El Paso increase when New Mexico pumping is turned off by an average of 61,100~~62,500~~ AF annually during 1951-2017, of which an average of 22,900~~24,800~~ AF occurs during the irrigation season and 38,200~~37,700~~ AF occurs during the non-irrigation season or during spills. Average annual flows at Fort Quitman during 1951-2017 increase by an average of 49,000~~49,900~~ AF due largely to return flows from increased surface water deliveries and reduced surface water depletions from pumping. This run shows that the Texas Model without reoperation greatly exaggerates the impacts of New Mexico pumping on El Paso flows.

30.3 TX Pumping Off (Run 4)

In Run 4, all supplemental irrigation pumping in EPCWID and HCCRD is turned off, as is all non-irrigation pumping and associated returns in the Texas portion of the Mesilla Valley and in the El Paso Valley. Deliveries of Project water to EPW and the associated return flows continue to be simulated in Run 4.

When Texas pumping is turned off, annual EBID diversions increase by an average of 5,400~~6,600~~ AF/y during 1951-1978, and by an average of 15,500~~20,400~~ AF during 2006-2017 when the 2008 OA is in effect. The impacts of Texas pumping are magnified by the sensitivity of changes in the diversion ratio on EBID allocations. The pattern of impacts on EBID FHG deliveries is similar with impacts to diversions that average 4,300~~4,900~~ AF during 1951-1978 and 9,600~~13,300~~ AF during 2006-2017.

Texas pumping also impacts Project water deliveries to EPCWID. The net effect on EPCWID supply depends on the relative positive effect of reducing depletions from pumping compared to the negative effect of turning off Texas WWTP discharges. During 1951-1978, EPCWID diversions increase by an average of 200~~3,100~~ AF, but FHG deliveries increase by an average of ~~only~~ 2,600~~800~~ AF. During the mostly full supply years of 1979-2005, EPCWID diversions increase by an average of 10,200~~11,900~~ AF to replace the significant reduction in WWTP discharges to the EPCWID canal system.

The reduction in the Texas WWTP discharges due to turning off the non-irrigation pumping and the concurrent increased deliveries of Project water to EPCWID, along with the reduction in stream depletions caused by Texas Mesilla irrigation pumping results in increased Rio Grande at El Paso flow in many years, particularly in the 1980s and 1990s. During 1985-2005, El Paso flows increase by an average of 27,800~~28,200~~ AF during the irrigation season, excluding spills.

30.4 MX Pumping Off (Run 5)

In Run 5, all supplemental pumping in JID and all municipal pumping and associated WWTP discharges in Ciudad Juarez is turned off. Turning off pumping in Mexico has much less effect on Project operations than turning off pumping in New Mexico or Texas.

Turning off Mexico pumping reduces the river and conveyance system losses in delivering Project water to EPCWID farmers. As a result, in full supply years, less water needs to be released from storage to meet EPCWID demands. This results in an accumulation of water in storage that increases allocations and deliveries in later non-full supply years. This is seen in the increased reservoir releases and deliveries in ~~1954,~~ 1955, 1964, 1967, ~~1971,~~ 1977, 1978 and several other years after 2000.

EBID FHG deliveries increase~~d~~ by an average of 2,400~~900~~ AF during 1951-1978, and 2,400~~1,900~~ AF during 2006-2017. EPCWID FHG deliveries increase~~d~~ by similar amounts averaging 1,500~~900~~ AF during 1951-1978 and 2,100~~1,800~~ AF during 2006-2017. The impact of Mexico pumping on the HCCRD supply is larger than on EBID or EPCWID, with the total irrigation season supply to HCCRD increasing by an average of 3,900~~4,800~~ AF during 1951-2007.

Mexico pumping also has a large impact on ground water storage in the Hueco. From 1951-2017, Hueco ground water storage is~~was~~ depleted by an average of 59,500~~59,700~~ AF/y. The effect of Juarez pumping from the new Conejos-Medanos wellfield is evident in the recent changes in Rincon-Mesilla ground water storage.

30.5 R-M Pumping Off (Run 6)

In Run 6, all irrigation pumping and non-irrigation pumping and associated returns in the Rincon and Mesilla basins is turned off. This includes turning off irrigation and non-irrigation pumping in the Texas portion of the Mesilla basin. The purpose of this run is to simulate a scenario that is~~was~~ directly comparable to the 100% reduced pumping run of the Texas Model described in the Hutchison Report.

As expected, the effect of turning off all Rincon-Mesilla pumping in Run 6 has a larger effect than turning off New Mexico pumping in Run 3, but with a similar pattern. Turning off R-M pumping increases the Project delivery efficiency by increasing drain flows, reducing river losses, and reducing canal seepage. In full allocation years, releases from storage can be reduced while still delivering full allocations to EBID and EPCWID. This accumulates water in storage leading to increased allocations and deliveries in dry years, and greater spills in very wet years.

As discussed in Section 18.0, the comparisons of simulated changes in El Paso flow between the ILRG Model and the Texas Model that were presented in the SWE Report were revised with results from the updated ILRG Model. The revised results are shown in revised **Figures 13-1** and **13-2** in **Appendix 18**.

Additional comparisons of the R-M Pumping Off results to comparable runs of the Texas Model presented in the Hutchison Report and the Second Supplemental Moran Report are presented in **Table 30-3**. These include comparisons of 1951-2016 averages for selected model outputs for the updated ILRG Model (Run 6), the Texas Model without reoperation (Hutchison; 100% R-M Pumping Off), and the Texas Model with crude redistribution~~reoperation~~ (Moran; 100% R-M Pumping Off). The updated ILRG Model results are summarized as annual averages and irrigation season averages. The Texas Model results are annual averages consistent with the annual stress periods in the Texas Model. The table entries for the Texas Model shown as “n/a” and shaded grey indicate outputs that are not simulated in the Texas Model.

Table 30-3 highlights many of the processes simulated in the ILRG Model that are not simulated in the Texas Model. It also contrasts long-term average differences between the models as to simulated changes in Rincon-Mesilla diversions and FHG deliveries, and El Paso flows. During 1951-2016, the average annual change in El Paso flow in the Texas Model is 124,700 AF without reoperation (Hutchison) and 51,700 AF with crude redistribution~~reoperation~~ (Moran). These results compare to the change in flow in the ILRG Model that averages 79,800~~79,500~~ AF year-around, and 33,200~~33,600~~ AF during the irrigation season, excluding spills. The change in flow goes down to ~~15,600~~12,900 AF during the irrigation season from 1985-2005.

30.6 TX Mesilla Pumping Off (Run 7)

In Run 7, all supplemental irrigation pumping and non-irrigation pumping in the Texas portion of the Mesilla basin is turned off. This includes turning off the EPW Canutillo wells and associated M&I return flows. The results of this run show that turning off Texas-Mesilla pumping has, on average over the whole study period, more impact on Project operations than does turning off all Texas pumping in Run 4. This is due to significant WWTP offsets that occur in Run 4.

Similar to many of the runs described above, turning off Texas-Mesilla pumping and returns increases the Project delivery efficiency due to increased drain flows, reduced river seepage, and reduced canal seepage. In turn, this reduces reservoir releases needed to deliver full supply allocations in wet years and the resulting storage accumulations increase allocations and deliveries in dry years.

Turning off Texas-Mesilla pumping causes EBID diversions to increase by an average of 7,200~~8,500~~ AF during 1951-1978 and 21,300~~21,300~~ AF during 2006-2017. EBID FHG deliveries increase in a similar pattern with average increases of 5,800~~6,800~~ AF in 1951-1978 and 12,500~~13,200~~ AF in 2006-2017. Impacts during recent years are magnified by the effect of the 2008 OA on EBID allocations.

EPCWID operations are also impacted by Texas-Mesilla pumping. Average irrigation season diversions by EPCWID increase by an average of 4,1005,800 AF during 1951-1978 and 2,6002,200 AF during 2006-2017. EPCWID FHG deliveries during 1951-1978 increase by an average of 2,0002,600 AF and during 2006-2017 by an average of 400300 AF.

30.7 TX Non-Irrigation Pumping Off (Run 8)

In Run 8, all Texas non-irrigation pumping and associated urban return flows are turned off. This includes pumping by EPW and other minor pumpers from the Hueco and pumping from EPW's Canutillo wellfield in the Mesilla Valley. Discharges from EPW's WWTPs are turned off except for amounts attributed to EPW's use of Project water which continue to be simulated. All urban deep percolation is also similarly eliminated or reduced.

Turning off the non-irrigation pumping and returns in Texas results in EPCWID ordering more Project water to replace the loss in WWTP discharge supply. This reduces the supply available for allocation in some dry years resulting in reduced diversions and/or deliveries to EBID and EPCWID. has a similar but smaller effect on Project operation compared to Run 4 in which all Texas pumping is turned off. Additional flow in the river from turning off the pumping allows the releases from storage to be reduced during full allocation years from 1958-1980. The accumulated additional stored water is allocated and released in dry years during this period. During the relatively wet period from 1980-2002, the loss of EPW WWTP discharges as an irrigation source causes increased releases from storage to meet EPCWID demands.

EBID diversions decreaseincrease by an average of 2,9001,600 AF during 1951-1978. with the increases occurring in years of less than full allocation when accumulated storage adds to the allocations. After the 2008 OA becomes effective, the increases in Project water diversions by EPCWID to replace the reduced WWTP discharge supply increases the computed diversion ratio resulting in and magnifies the effects of Texas pumping, EBID diversions increasinge by an average of 12,10016,300 AF during 2006-2017. EBID FHG deliveries changeincrease by corresponding amounts with an average decreasesincreases of 1,0001,900 AF from 1951-1978 and an average increases of 7,60011,100 AF from 2006-2017. The increase in EBID FHG deliveries is greater than the increase in EBID diversions during 1951-1978 because the reduction in Texas Mesilla pumping reduces EBID canal losses allowing more of the water that EBID diverts to be delivered to the farms.

Turning off Texas non-irrigation pumping causes EPCWID to order more Project water to replace the lost WWTP returnshas a significant effect on EPCWID supply. There is a modest increase in diversions during 1951-1978 averaging 2,5001,200 AF/y, which . This is followed by a much larger increase in diversions during 1979-2005 averaging 14,300~~13,500~~ AF/y.

30.8 NM Non-Irrigation Pumping Off (Run 9)

In this scenario, all non-irrigation pumping in New Mexico along with the associated WWTP discharges and urban deep percolation are turned off. The effects are similar in pattern, but much smaller than the effects of turning off all New Mexico pumping in Run 3.

The familiar pattern of accumulated water in Project storage in wet years followed by increases in allocation and releases in dry years is repeated in Run 9. EBID diversions increase by averages of 2,500~~2,500~~ AF during 1951-1978 and 23,400~~21,100~~ AF during 2006-2017 when the effects of pumping are elevated by interaction with the revised allocation procedure under the 2008 OA. EBID FHG deliveries increase proportionally by an average of 2,000~~2,000~~ AF/y during 1951-1978 and 14,100~~13,700~~ AF/y during 2006-2017.

EPCWID diversions and FHG deliveries increase by small amounts when the non-irrigation pumping in New Mexico is turned off. On average, irrigation season diversions for EPCWID increase by 900~~1,300~~ AF during 1951-1978 and 4,500~~2,500~~ AF during 1985-2017. Irrigation season FHG deliveries to EPCWID increase by 800~~1,000~~ AF from 1951-1978 and 2,000~~1,400~~ AF during 1985-2017.

The increases in Rio Grande at El Paso flow during the irrigation season are generally limited to times of increased deliveries to EPCWID, and these average 4,000~~2,800~~ AF during 1951-2017. ~~There are larger~~ The increases in El Paso flow during the non-irrigation season and during spills ~~that~~ average 2,100~~3,400~~ AF during 1951-2017.

~~This run shows that New Mexico M&I pumping has a relatively small effect on EPCWID diversions and deliveries to Texas water users. In sum, when New Mexico's non-irrigation pumping is turned off, EPCWID diversions only increase on the range of 9001,300 AF/yr (1951-1978) to 5,3002000 AF/yr (1985-2005) in the years prior to the implementation of the 2008 OA.~~

30.9 MX Non-Irrigation Pumping Off (Run 10)

In this scenario, all non-irrigation pumping for Ciudad Juarez in Mexico along with the associated sewage/WWTP returns are turned off. Mexico non-irrigation pumping has a relatively minor effect on Project operations and deliveries to EBID and EPCWID. For the analysis of all Mexico groundwater pumping off, refer to Run 5 in section 30.4 above.

Mexico irrigation pumping increases due to loss of Juarez WWTP discharges. This in turn increases EPCWID conveyance losses resulting in EPCWID having to increase diversions to deliver similar amounts to the farms. EPCWID irrigation season diversions increase by an average of 700700 AF/y during 1951-2017, andbut FHG deliveries decreaseincrease by an average of 200500 AF over the same period. The increase in EBID diversions and FHG over 1951-2017 is minimal averaging 300100 AF.

30.10 2008 Operating Agreement Scenarios (Runs 11 and 12)

Two runs of the ILRG Model were made to evaluate the effect of the D3+Carryover accounting in the 2008 OA on Project operations and LRG water supplies. In Run 11, the D1/D2 allocation procedure is simulated to allocate Project water during the entire period from 1950 - 2017 period, and in Run 12 the D3+Carryover accounting is simulated during this 68-year period[5]. Otherwise, both runs employ the same RiverWare simulation rules that are used in the Historical Base Run. Irrigation pumping is computed based on the unmet irrigation demand and the non-irrigation pumping and associated return flows are set at historical levels.

Comparison of the results of Run 11 to Run 1 show the effects of the 2008 OA on Project operations in Run 1 compared to what would have happened had the 2008 OA not been implemented and the D1/D2 allocation procedure been left in place.

When the D1/D2 allocation procedure is left in place during 2006-2017, the annual allocations to EBID increase substantially in most years during this period resulting in large increases in EBID diversions averaging 94,200103,200 AF and in EBID FHG deliveries averaging 54,60064,100 AF. These impacts on EBID from the 2008 OA are far greater than the impacts of New Mexico pumping on EPCWID irrigation season FHG deliveries that average 17,80014,900 AF during 2006-2017 as shown in the Run 3 results.

Conversely EPCWID diversions decline by an average of 23,00028,900 AF and FHG deliveries decline by an average of 17,20022,200 AF during 2006-2007. The reason for the decline in EPCWID supply is primarily due to the limited amount of Project water in storage. The increases in EBID's allocations and deliveries result in smaller amounts of Project water to allocate between the districts in subsequent years. Another factor is the absence of carryover for the individual districts and this results in more water allocated to EBID and less water available for EPCWID to use.

---

[5] The RiverWare rules do not simulate annual allocations during the wet period from 1940 – 1949.

ATTACHMENT 17A

Comparison of the results of Run 12 to Run 11 allows differences between the D1/D2 and D3+Carryover allocation procedures to be evaluated over the entire 1950-2017 period. The differences between these runs are computed based on Run 12 (D3+CO) minus Run 11 (D1/D2) and therefore reflect the impacts of going from the D1/D2 allocation procedure to the D3+CO allocation procedure.

Comparison of Run 12 and Run 11 shows clearly the effect of the 2008 OA on EBID varies depending on the type of year. In wet years with a relatively high diversion ratio, the annual EBID allocation is greater under the D3+CO method than under D1/D2 method and this results in increased diversions and FHG deliveries during 26 of the 67 years between 1951-2017 period (1951-1952, 1959-1962, 1982-2001). EBID diversions and FHG deliveries were lower in the other 41 years which were generally years of average and below average water supply. On average during 1951-2017, EBID diversions declined by 34,40037,600 AF and FHG deliveries declined by 19,80022,100 AF.

Conversely, the 2008 OA has a positive effect on EPCWID allocations, diversions, and FHG deliveries in most years. During the irrigation season, diversions increased by an average of 13,10015,300 AF and FHG deliveries increased by an average of 8,20010,700 AF. The average increase in EPCWID supply is much less that the average decrease in EBID supply.

The following is a summary of the average annual effect on EBID and EPCWID FHG deliveries in dry, wet, and all years duringthree intervals of the 1951-2017 period.

ATTACHMENT 17A

Cumulative Volume Impact of 2008 Operating Agreement on March - October FHG Deliveries In Wet and Dry Periods 1951-2017

Condition	Years	EBID	EPCWID
Dry	1953-1958, 1963-1981, 2002-2017	-2.47-2.74 MAF	+0.37+0.47 MAF
Wet	1951-1952, 1959-1962, 1982-2001	+1.141.26 MAF	+0.17+0.25 MAF
All	1951-2017	-1.33-1.48 MAF	+0.55+0.71 MAF

The results in the above table show that the 2008 OA takes away critical surface water in the dry years when EBID has a greater need for water (2.472.74 MAF) than it gives back to EBID in wet years when the need is less (1.141.26 MAF) As a result, the 2008 OA forces EBID to pump more ground water in dry years to make up for the reduction in surface water supplies. The increased EBID pumping negatively affects the diversion ratio which contributes to the reduction in water allocated and delivered to EBID in dry years. This was termed a "vicious cycle" by Dr. Barroll (2019, 2020a).

30.11 Reduced Waste (Run 13)

As was described in Section 5.0 of the SWE Report, beginning with the 1950s drought and continuing through the 1970s, Reclamation was able to operate the Project with reported operational waste below 10% during most years. In a few years during the wet periods of the mid-1980s and mid-1990s, the EBID waste increased to approximately 20%. The situation in EPCWID was markedly different than in EBID from the 1980s through the 2000s (after EPCWID took over operations) with the operational waste consistently in the range of 20% to 30%.

A run of the ILRG Model was made to evaluate the benefit to the Project from reducing the operational waste. The RiverWare operational rules were modified so that the operational waste was limited to the lesser of the historical amounts or 10% of the simulated diversions.

Limiting operational waste in both Districts to no more than 10 percent reduces releases from Project storage in full allocation years resulting in increased allocations and deliveries in dry years with less than full allocations. As a result of the more efficient

Project operation, FHG deliveries to EBID and EPCWID increase~~occur~~ in many years during the 1950s – 1970s, and again after 2002. Increases in FHG deliveries to EBID average~~d~~ 35,300~~36,100~~ AF during 1951-1978 and 57,300~~48,900~~ AF during 2006-2017. Increases in FHG deliveries to EPCWID average~~s~~ 17,800~~30,700~~ AF during 1951-1978 and 18,500~~20,600~~ AF during 2006-2017.

30.12 Hueco Pumping Off (Runs 14, 14a, 14b, 14c, and 14d)

In response to questions from Texas legal counsel during depositions of the New Mexico experts, and in response to opinions from Texas and U.S. experts, several runs of the ILRG Model were made in which all or a portion of the pumping in the Hueco was turned off, as well as runs in which pumping was turned off without turning off WWTP discharges and vice-versa. The results from these runs are useful in assessing the effects of the Hueco pumping in isolation from pumping in other areas of the LRG basin and the effect of WWTP discharges in offsetting impacts from Hueco pumping.

The No Hueco Pumping Scenarios is~~were~~ simulated in the same manner as the other no pumping scenarios. The supplemental irrigation pumping from the Hueco in Texas and/or Mexico is~~was~~ turned off. In addition, the non-irrigation pumping in these areas and the corresponding WWTP and urban deep percolation return flows are~~were~~ also turned off. Specifications and summaries of the results of the No Hueco Pumping Scenarios are presented below. Runs 14a, 14b, 14c, and 14d were made to test various components of Run 14.

- All Hueco Pumping Off (Run 14) – In Run 14, all supplemental irrigation pumping and non-irrigation pumping in the Hueco in Texas and Mexico is~~was~~ turned off. In addition, the WWTP discharges by EPW and Ciudad Juarez from their Hueco pumping are~~were~~ turned off, as is~~was~~ the urban deep percolation from EPW[6].

  There are opposing effects within EPCWID from turning off Hueco pumping. Turning off Hueco pumping reduces canal and lateral losses in EPCWID and reduces river seepage between American Dam and Riverside Dam before the ACE was constructed in 1999. These changes can result in reduced Project water orders to deliver the same amount of water to EPCWID farm headgates. On the other hand, the reduction in WWTP discharges to the EPCWID canal system when M&I pumping is turned off reduces the irrigation supply available to deliver to EPCWID farm headgates and increases RHG demands for Project water. These

[6] No urban deep percolation is simulated for Mexico in the historical Base Run.

opposing effects can result in net increases or decreases in annual EPCWID FHG deliveries.

The effects within EPCWID from turning off Hueco pumping can propagate upstream and impact reservoir operations and deliveries to EBID depending on whether it is a full allocation year or non-full allocation year. In full allocation years, there is little effect on EBID FHG deliveries because EBID's allocation does not change. In non-full allocation years, accumulated changes in reservoir storage resulting from changes in EPCWID orders of Project water can result in changes in EBID allocations and deliveries.

When Hueco pumping is turned off in Run 14, there are some increases and decreases in EBID FHG deliveries that average to a 1,500~~300~~ AF increase during 1951-2017 with the increases occurring in dry years. ~~After the 2008 OA goes into effect, turning off Hueco pumping has a larger benefit to EBID, with FHG deliveries increasing by an average of 9002,300 AF during 2006-2017, with a few years of increases exceeding 10,000 AF~~. ~~The increases in recent years are elevated due to the effect of Hueco pumping on the diversion ratio and the sensitivity of the EBID allocation to changes in the diversion ratio.~~

Turning off Hueco pumping increases~~reduces~~ EPCWID FHG deliveries by an average of 800~~1,200~~ AF during 1951-2017. Turning off Hueco pumping results in a substantial increase in the total HCCRD supply (RHG diversions) averaging 7,500~~10,900~~ AF during 1951-2017.

- Texas Hueco Pumping Off (Run 14a) – In Run 14a, all supplemental irrigation pumping and non-irrigation pumping by Texas in the El Paso Valley is~~was~~ turned off, along with the WWTP discharges and urban deep percolation from the EPW Hueco pumping.

  Turning off Texas Hueco pumping reduces EBID FHG deliveries by an average of 1,000~~100~~ AF during 1951-2017. ~~However,~~ EBID FHG deliveries decrease~~increase~~ by an average of 4,000~~1,600~~ AF during 2006-2017 when the 2008 OA is in effect.

  During 1985-2017, Texas Hueco pumping reduces EPCWID FHG deliveries during the irrigation season by an average of 1,400~~1,700~~ AF and increases the total flow to HCCRD an average of 2,100~~2,300~~ AF.

  Contrary to the claims of the Texas and U.S. experts, the impacts of Texas Hueco pumping on Project operations and surface water supplies to EBID, EPCWID, and HCCRD are not negligible.

- Mexico Hueco Pumping Off (Run 14b) – In Run 14b, all supplemental irrigation pumping and non-irrigation pumping in the Mexico portion of the Hueco iswas turned off, along with the WWTP discharges from Ciudad Juarez pumping.

  Turning off Mexico pumping reduces canal seepage and river seepage in EPCWID causing reduced Project orders at EPCWID canal headings. This results in accumulation of water in Project storage that increases Project water deliveries to EBID in years with less than a full Project water allocation. Simulated increases in EBID FHG deliveries average 1,700800 AF during 1951-2017, and 3,2001,900 AF during 2006-2017, with increases exceeding 5,000 AF in several years and 10,000 AF in 20102013.

  Turning off Mexico Hueco pumping has similar effects on EPCWID with FHG deliveries increasing by an average of 1,500800 AF during 1951-2017. The increase in total HCCRD supply is greater averaging 4,8003,900 AF during 1951-2017.

- Texas WWTP Discharges Off (Run 14c) – In Run 14c, all discharges from Texas WWTPs arewere turned off. This includesd turning off discharges from the EPW's Northwest, Haskell, Socorro, and Bustamante WWTPs, as well as discharges from the Anthony TX WWTP and the Fabens WWTP. The purpose of this run iswas to quantify the benefit to the Project operations and LRG water users from the Texas WWTP discharges. Without these discharges, the impacts of Texas Hueco pumping would be much larger.

  When the Texas WWTP returns are turned off, EBID FHG deliveries decrease markedly in numerous years with less than full allocations. This shows the interconnected nature of the Project and how changes in supply at the bottom of the Project area can ripple through the Project and affect operations hundreds of miles upstream. On average during 1951-2017 the reduction in diversions averages 14,6009,500 AF and the reduction in FHG deliveries averages 6,6004,700 AF.

  Turning off Texas WWTP discharges results in increased Project releases and diversions to EPCWID to replace the reduction in irrigation supply to EPCWID farmers from the WWTP discharges. This results in large increases in El Paso flows to deliver additional Project water to EPCWID, particularly during the wet period in the 1980s and 1990s. The increase in El Paso flows during the irrigation season, excluding spills, average 38,30036,300 AF during 1985-2005.

Without the Texas WWTP discharges, the simulated impacts from Texas pumping would be much larger than the impacts shown in Runs 4, 7, 8, 14, and 14a. The results for Run 14c show the effect of Texas WWTP discharges have in offsetting the impacts of Texas pumping. Without these discharges (for example if EPW reused its WWTP discharges for non-potable uses), the effects of Texas pumping on Project operations, including deliveries to EBID would be much greater.

- Texas Hueco Pumping Off without WWTP Discharges Off (Run 14d) – In Run 14d, Texas Hueco pumping is~~was~~ turned off without turning off the associated Texas WWTP discharges and urban deep percolation. This test run simulates the effect of Texas Hueco pumping without the offsets from Texas M&I return flows.

  When the Texas Hueco pumping is turned off without turning off the M&I returns, the simulated impacts on Project operations increase. EBID FHG deliveries increase by an average of 5,000~~1,900~~ AF during 1951-1978 and 2,000~~2,800~~ AF during 2006-2017. FHG deliveries to EPCWID increase by 4,600~~6,200~~ AF during 1951-1978 and 2,000~~2,500~~ AF during 2006-2017. Total flows to HCCRD increase by 7,100~~9,700~~ AF during 1951-1978 and 3,700~~3,200~~ AF during 2006-2017.

30.13 Early EPCWID Ops (Runs 15, 15a, 15b, 15c)

Four scenarios were simulated using the ILRG Model to evaluate the effects on Project operations that would result from a return to EPCWID operations consistent with how the Project was operated in the past. These include simulating increased irrigation use of drain flows in the Fabens area and charging EPCWID for all water that it uses. Runs 15a, 15b, and 15c were made to test various components of Run 15. Descriptions of the four Early EPCWID Ops scenarios are provided below along with the scenario results.

- Early EPCWID Ops (WWTP & Fabens Drains) (Run 15) – In Run 15, simulation of EPCWID operations in the El Paso Valley are~~were~~ modified to simulate irrigation use of all available supplies consistent with how the Project was originally operated in the El Paso Valley. This includes simulation of irrigation use of the usable Fabens drain flows, which are~~were~~ estimated as 70% of the total Fabens drain flows limited to a monthly volume of 6,000 AF, based on available historical data (see response to Ferguson Opinion 9 for more information). In addition, EPCWID is charged for all use of drain flows and WWTP flows, and the ACE Credit and Haskell WWTP discharge credits are disabled. These changes reflect operations consistent with the original concept and implementation of the Project which was to use all available supplies ~~in the river~~ to minimize the amount of storage releases needed to meet Project water demands. Further, since EPCWID is charged for all of its water use including the water that arises within the EPCWID system, it has less unused allocation in many years and uses its entire allocation in more years than in the Historical Base Run (Run 1). The increased use of water arising within the EPCWID system reduces the releases from Project storage to meet EPCWID demands and the accumulated Project storage increases the supply available for allocation and use in subsequent years. When accounting under 2008 OA commences, EPCWID has less unused allocation to carryover to subsequent years. The following is a summary of the effects of the foregoing changes in EPCWID operations:

- EBID – FHG deliveries increase modestly by an average of 4,3004,500 AF during 1951-1978 and by a much larger amount, averaging 41,90037,800 AF, during 2006-2017. The large increases during the recent period result from significant increases in the diversion ratio that result from EPCWID being charged for all water that it uses, and the positive feedback of increases in the diversion ratio on EBID allocations under D3 accounting.

- EPCWID – FHG deliveries increase by an average of 1,4003,100 AF during 1951-2017. Simulated EPCWID RHG diversions decrease by an average of 15,10012,100 AF during 1951-2017 as diversions of Project water from the river are eschewed in favor of the supplies arising within EPCWID.

- HCCRD – The changes in EPCWID operations result in minor reductions in the water flowing to HCCRD. Annual total flow to HCCRD decreases by an average of 3,1002,100 AF during 1951-2017.

- Early EPCWID Ops (WWTP) (Run 15a) – In Run 15a, EPCWID is charged for irrigation use of WWTP flows, and the ACE Credit and Haskell WWTP discharge credits arewere disabled. However, the simulated use of drain flows is left at the historical levels simulated in Run 1, and EPCWID is not charged for the historical use of the drain flows. The results are similar in pattern to the Run 15 results but smaller in magnitude as follows:

  - EBID – FHG deliveries increase modestly by an average of only 200400 AF during 1951-1978, but by much larger amounts averaging 27,20023,600 AF during 2006-2017. Similar to Run 15, the large increases during the recent period result from the effect of an increase in the diversion ratio on EBID allocations under the 2008 OA.

  - EPCWID – FHG deliveries decrease by an average of 1,9001,800 AF during 1951-2017. Simulated EPCWID RHG diversions decrease by an average of

2,9002,800 AF during 1951-2017 with the increased use and charge for supplies arising within EPCWID.

- HCCRD – Charging EPCWID for use of WWTP flows and elimination of credits against charges reduces the total flow to HCCRD by an average of 500700 AF during 1979-2005 and 2,2002,500 AF during 2006-2017

- Early EPCWID Ops (Fabens Drains) (Run 15b) – In Run 15b, the model simulates and charges EPCWID for use of the usable Fabens drain flows as described above in Run 15. However, EPCWID is not charged for use of WWTP flows and is credited for Haskell WWTP discharges and the ACE Credit. The results are similar in pattern to the Run 15 results as follows:

  - EBID – FHG deliveries increase modestly by an average of 4,3004,200 AF during 1951-1978, and by an average of 21,80017,000 AF during 2006-2017. Similar to Run 15, the large increases during the recent period result from the effect of an increase in the diversion ratio on EBID allocations under the 2008 OA.

  - EPCWID – FHG deliveries increase by an average of 3,1005,300 AF during 1951-2017. Simulated EPCWID RHG diversions decrease by an average of 12,9009,100 AF during 1951-2017 with the simulated increased use and charge for drain flows arising within EPCWID.

  - HCCRD – The increased use of drain flows in EPCWID results in a reduction in the total flow to HCCRD averaging 2,6001,300 AF.

- Early EPCWID Ops (TX Hueco Pumping Off) (Run 15c) – In this scenario, the changes to EPCWID operations and accounting from Run 15 were simulated with the Texas Hueco pumping turned off. The effects of Texas Hueco pumping with the modified EPCWID operation were assessed by comparing the results of Run 15c and Run 15. The effects of the Texas Hueco pumping on EBID are mixed due to the opposing effects on EPCWID from pumping and WWTP discharges from pumping.

30.14 Conj Use 1: Hist All Acres D1/D2 (Runs 16 and 16a)

Two scenarios arewere simulated to evaluate conjunctive use of surface water and ground water within the Rio Grande Project under the D1/D2 allocation procedure with the historical irrigated area that evolved over time (including irrigation of the primary ground water only acres in New Mexico), and with the early EPCWID operations that arewere simulated in Run 15. In both scenarios, irrigation pumping in EBID and EPCWID is limited based on the irrigation pumping that existed during the 1951-1978 D1/D2 data period. This is implemented by not allowing the 10-year running average pumping after 1978 to exceed the 1951-1978 historical average annual pumping.

- Conj Use 1: Hist All Acres D1/D2 (Hist M&I) (Run 16) – Run 16 essentially combines the early EPCWID operations from Run 15 with the Run 11 continuation of D1/D2 allocation of Project water after 2005 along with a limit on irrigation pumping after 1978. In Run 16, the M&I pumping and returns are set at the historical amounts simulated in Run 1. The results for Run 16 are very similar to Run 15 until 2005. After that time, the differences from Run 1 represent the combination of the early EPCWID operations and continuation of D1/D2 accounting. The following are summaries of the differences between Run 16 and Run 1 after 2005:
    - EBID – FHG deliveries increase by an average 69,00078,300 AF during 2006 -2017 which is much greater than the increase of 41,90037,800 AF in Run 15.
    - EPCWID – FHG deliveries decrease by an average of 14,50020,100 AF during 2006 -2017 with the D1/D2 accounting compared to an average increasedecrease of only 700400 AF decrease in Run 15.
    - HCCRD – Total flows to HCCRD decline by an average of 9,50011,700 AF during 2006-2017, compared to an average decline of 3,8003,800 AF during this same period in Run 15.
- Conj Use 1: Hist All Acres D1/D2 (1978 M&I) (Run 16a) – The conditions simulated in Run 16a are the same as Run 16 except that M&I pumping in New Mexico and Texas after 1978 is limited to the levels that existed in 1978 at the end of the D1/D2 period. This limit has minimal effect on Texas M&I pumping because it exceeded the 1978 amount by only small amounts in a few years after 1978. When the M&I pumping is limited by the 1978 amount, the simulated M&I returns are scaled down proportionally. The results of Run 16a are very similar to Run 16 which reinforces that New Mexico M&I pumping has relatively little impact on Project operations.

- o EBID – FHG deliveries increase by an average of 72,40080,700 AF during 2006-2017 compared to an average increase of 69,00078,300 AF in Run 16.
- o EPCWID – FHG deliveries decrease by an average of 12,60018,500 AF during 2006-2017 compared to a decrease of 14,50020,100 AF in Run 16.
- o HCCRD – Total supply to HCCRD from 2006-2017 decreases by 9,20011,100 AF compared to an average decrease of 9,50011,700 AF in Run 16.

30.15 Conj Use 2: Hist Proj Acres (Runs 17 and 17a)

A second set of conjunctive use scenarios are simulated in Run 17 and Runs 17a under the D1/D2 allocation procedure with irrigation limited to the historical Project acres and no irrigation of the non-Project primary (ground water only) acres in New Mexico. The early EPCWID operations from Run 15 are also a part of these conjunctive use scenarios.

- Conj Use 2: Hist Proj Acres (Hist M&I) (Run 17) – In Run 17, the M&I pumping and returns are set at the historical amounts simulated in Run 1. The results from Run 17 are similar to the results from Run 16 and the differences largely reflect the effect of ground water pumping on primary acres in New Mexico.
  - o EBID – Annual FHG deliveries increase by an average of 7,5009,300 AF during 1951-1978, and by a much larger average of 75,60082,600 AF following the change to D1/D2 after 2005.
  - o EPCWID – Annual FHG deliveries increase by an average 5,1006,300 AF during 1951-1978, and decline by 10,70016,200 AF during 2006-2017 due to the change in allocation method from D3 to D1/D2 starting in 2006.
  - o HCCRD – Total flows to HCCRD decrease by an average of 8,6009,600 AF during 2006-2017.
- Conj Use 2: Hist Proj Acres (Pre-Comp M&I) (Run 17a) – The conditions simulated in Run 17a are the same as Run 17 except that M&I pumping in New Mexico and Texas is set at the pre-Compact amounts that existed in 1938 (736 AF/y in New Mexico and 13,744 AF/y in Texas). M&I returns are scaled down proportionally consistent with the pre-Compact pumping volumes. The differences between Run 17 and Run 17a reflect the effects of the post-compact increases in total M&I pumping throughout the study area on simulated surface water supplies.
  - o EBID – Annual FHG deliveries increase by an average of 9,50013,500 AF from 1951 – 1978 and 87,90093,400 AF from 2006-2017. These compare

to an increase of 7,5009,300 AF and an increase of 75,60082,600 AF in Run 17, respectively.

- o EPCWID – Annual FHG deliveries increase by an average 6,1001,700 AF during 1951-1978, and decrease by 4,3009,900 AF during 2006-2017 due to the change in allocation method to D1/D2. These compare to a 1951-1978 increase of 5,1006,300 AF and 2006-2017 decrease of 10,70016,200 AF in Run 17.
- o HCCRD – Total supply to HCCRD increases by an average of 1,1002,800 AF during 1951-2017 compared to an average decrease of 2,8002,300 AF in Run 17.

30.16 Conj Use 3: Auth Proj Acres (Pre-Comp M&I) (Run 18)

A third conjunctive use scenario is simulated in Run 18 under the D1/D2 allocation procedure with irrigation of the original authorized Project acres simulated in every year from 1940-2017 (88,000 acres in EBID and 67,000 acres in EPCWID). The irrigated area in HCCRD is set at the reported maximum historical amount of 17,750 acres that occurred in 1951, and the irrigated area in JID is set at historical levels. M&I pumping and returns arewere limited to the pre-Compact amounts as in Run 17a. The early EPCWID operations are also simulated as in the other conjunctive use scenarios. Finally, because the authorized EPCWID acres are simulated as irrigated in every year, there is no simulation of EPW use of Project water.

- EBID – Annual FHG deliveries decreaseincrease by an average of 1,8002,700 AF during 1951-1978, and increase by 51,50064,300 AF during 2006-2017 under D1/D2.
- EPCWID – Annual FHG deliveries increasedecrease by an average of 5,6004,000 AF during 1951-1978 and decrease by an average of 35,70038,650 AF during 2006-2017 when allocations revert back to the D1/D2 method.
- HCCRD – Total supply to HCCRD increases by 5001,200 AF during 1951-1978 and decreases by an average of 13,50013,700 AF during 2006-2017.

Appendix 27
Inputs for Hueco Annual CFB Models
1903 – 1937

1. Introduction

The CFB Models contain canal and farm budget calculations on an annual time-step for units overlying the Hueco ground water basin, including EPCWID (El Paso Valley), HCCRD, and JID Units 1 – 3. The annual Hueco CFB Models are from 1903 – 1937. This appendix describes the inputs used in the annual Hueco CFB Models.

2. Annual Hueco CFB Model Inputs

2.1 Surface Water Supplies

Surface water supplies were input into the CFB Models using flow data from the surface water dataset ("SWDataSet") and accounting dataset prepared by SWE. The following table summarizes the annual surface water supplies used in the annual Hueco CFB Models for the 1903 – 1937 period.

Irrigation Unit	Surface Water Supplies (1903 – 1937)
EPCWID (El Paso Valley)	1903-1919, 1922, 1924-1926, 1928-1930, 1932, and 1935: Franklin Canal (1903 – 1937) - Ascarate Wasteway (1916 – 1937) + Riverside Canal (1928 – 1937) 1920-1921, 1923, 1927, 1931, 1933-1934, 1936-1937: Reported annual total diversion from WDR reports.
HCCRD	1915 – 1923: Calculated (irrigated acres x 4 feet) 1924 – 1937: Tornillo Canal Waste End + Tornillo Drain
JID Unit 1 JID Unit 2 JID Unit 3	Acequia Madre (1903 – 1937) + Cuidad Juarez Sewage (1926 – 1937) + River Diversions (1907 – 1937); split proportionally between units using irrigated acreage

Available surface water flows from 1903 – 1937 have been compiled, but there are significant data gaps during this period. SWE coordinated with MMA to estimate the missing 1903 – 1937 annual data. The start dates for different canals, wasteways, and drains were provided by MMA. These estimates are described in detail below.

EPCWID (El Paso Valley) 1903 – 1937

Annual data for the Franklin Canal date back to 1914 (missing data in 1917). Prior to the construction of the American Dam in 1938, the Franklin Canal diverted at the International Dam. Franklin Canal diversion data from 1903 – 1913 and 1917 were estimated using an annual 1918 – 1938 regression with streamflows for the Rio Grande at El Paso gage. The Franklin Canal diversions were estimated as the minimum of the computed canal flow using the regression and the estimated capacity of the canal (320 cubic feet per second ["cfs"]). The Franklin Canal diversions were also limited to an irrigation season of March to November.

The Ascarate Wasteway was constructed around 1916, but annual flow records are only available after 1938. Annual Ascarate Wasteway flows from 1916 – 1937 were estimated using a 1938 – 1949 annual regression with the Franklin Canal.

The Riverside Canal was constructed around 1928 and the annual records for the Riverside Canal from 1928 – 1937 are complete.

HCCRD 1903 – 1937

Irrigation in HCCRD commenced around 1915 with the construction of ditches that diverted water from the Rio Grande and HCCRD was organized in 1924 (Reclamation, 2013). HCCRD flows were measured starting in the 1920s. Measurement of the Tornillo Drain flows began in 1923 and measurement of the Hudspeth Canal (Tornillo End) began in 1925. The total flow to HCCRD was assumed to be the sum of the Tornillo Drain and the Hudspeth Canal (Tornillo End). According to the HCCRD water supply schematic (see SWE Report Figure 6-4; Sullivan and Welsh 2019), the Hudspeth Canal (Tornillo End) began in 1925. There are no Hudspeth Canal (Tornillo End) flow records from 1925 – 1934 and only annual data are available 1935 – 1937. The Hudspeth Canal (Tornillo End) flows are estimated from 1925 – 1934 using a water balance approach, calculated as the Tornillo Canal heading flow minus an assumed seepage loss minus farm headgate demands for the Tornillo acres minus Tornillo Waste. Annual Hudspeth Canal (Tornillo End) flows are distributed monthly using the same distribution as the Tornillo Canal heading monthly flows.

Various regression equations to estimate diversions for the Tornillo Drain and Hudspeth Canal (Tornillo End) from 1915 – 1923 were tested and did not yield good fits. Therefore, the diversions from 1915 – 1923 were estimated as the total irrigated acres multiplied by four feet.

JID Units 1 – 3 1903 – 1937

Diversion records for Acequia Madre are available from 1924 – 1925 and 1930 – 1936. Missing data for 1903 – 1923, 1926 – 1929, and 1937 were estimated using an annual 1930 – 1936 regression with the Rio Grande at El Paso gaged flows. The Acequia Madre diversions were estimated as the minimum of the computed canal flow using the regression and the estimated capacity of the canal (300 cfs). The Acequia Madre diversions were also limited to an irrigation season of March to November. A water balance calculation was conducted to check that the estimated combined diversions at Franklin Canal and Acequia Madre did not exceed the total Rio Grande flow at El Paso gage.

The Sewage Flow from 1926 – 1937 was estimated to be 49 percent of the Cuidad Juarez (“JMAS”) pumping using methodology described in the report**.** There are no data for JMAS pumping prior to 1926, although the annual JMAS pumping was less than 500 acre-feet in the late 1920s. Because of the lack of data and the small magnitude of the JMAS pumping, no Sewage Flows were computed to include in the surface water supply to Juarez prior to 1926. Sewage Flow available to the farms from 1926 – 1937 was limited to the irrigation season of March to October.

Annual estimates of River Diversions from 1930 – 1936 from the 1938 Rio Grande Joint Investigation (“RGJI”) were used in the CFB Models (USNRC, 1938). Due to similar hydrological conditions, annual data for 1937 was assumed to be equal to 1936. The River Diversions prior to 1930 were computed as the estimated available river flow limited to the JID irrigation demand.

The total JID water supplies from 1903 – 1937 were distributed to the JID units based on the irrigated area in each unit. This distribution of water is consistent with the water distribution used during this period in Carreno (1957), except in the drought years 1903 – 1906 in which water was assumed to only be available to JID Unit 1.

2.2 Irrigated Area

Available irrigated area data from 1903 – 1937 were compiled for use in the annual Hueco CFB Models. There are no data on primary acres in Texas and Mexico and all irrigated lands for these areas are assumed to be supplemental acres.

Available irrigated area in Texas, EPCWID (El Paso Valley) and HCCRD, from 1903 – 1937 are from the 1938 RGJI. The 1938 RGJI records are not complete from 1903 – 1937, and missing irrigated area data were estimated using interpolation/extrapolation of the years with data. The reported and estimated irrigated acreage data used in the CFB Models are shown in the table below.

The irrigated area data for JID was obtained from various reports (USNRC, 1938 and IBWC, 1989). Similar to EPCWID (El Paso Valley) and HCCRD, the irrigated acreage for years of no data were interpolated between the available reported acreage. The total acreage was distributed into the three JID units primarily using the reported distribution from Carreno (1957), except from 1903 – 1906, it was assumed that during low flows all diversions would go to JID Unit 1. In 1904, it was assumed that there were zero irrigated acres since there were no flows at the Rio Grande at El Paso gage that year from March – July.

The irrigated area used in the annual Hueco CFB Models is summarized in the table below.

District	Supplemental Acres 1903 – 1937
EPCWID (El Paso Valley)	1903 – 1906: Set equal to 1907 acreage from RGJI (USNRC, 1938) 1907, 1914, and 1920 – 1935: Acreage from RGJI (USNRC, 1938) 1908 – 1913: Linear interpolation between 1907 and 1914 acreage from RGJI (USNRC, 1938) 1915 – 1917: Set equal to 1914 acreage from RGJI (USNRC, 1938) 1918 – 1919 and 1936 – 1937: Reclamation Water Distribution Reports (Accounting DataSet)
HCCRD	1903 – 1914: Assumed zero irrigated acres (MMA) 1915 – 1919: Linear interpolation between zero acres in 1914 to 1920 acreage from RGJI (USNRC, 1938) 1920 – 1936: Acreage from RGJI (USNRC, 1938) 1937: Davids Engineering (2018)
JID Units 1 – 3	1903, 1905, 1908 – 1914, 1916 – 1922, 1927 – 1929, and 1931 – 1937: Acreage interpolated from IBWC (1989) and RGJI (USNRC, 1938), data provided by MMA 1904, 1906, 1915, and 1930: Acreage from IBWC (1989), data provided by MMA 1907 and 1923 – 1926: Acreage from RGJII (USNRC, 1938), data provided by MMA

2.3 Crop Irrigation Requirement and Excess Effective Precipitation

For the 1903 – 1935 annual Hueco CFB Models, the CIR is the average annual 1936 – 1937 CIR from DE reduced by 5 percent. For 1936 – 1937, the annual CIR from DE was reduced by 5 percent. There is no assumed excess effective precipitation simulated in the 1903 – 1937 annual CFB Models.

2.4 Conveyance and Other Losses

For the HCCRD and JID CFB Models, the total canal loss and wasteway flows loss is a user-specified percent of the total diversions for each annual CFB Model. These percentages do not vary from year-to-year. The total canal loss is set to 40% for the HCCRD and JID CFB Models from 1903 – 1937. The wasteway flow percentage is set to 0%.

For the EPCWID (El Paso Valley), the canal loss and waste are user-specified percentage (40% and 10%) for years with no WDR records (1903-1919, 1922, 1924-1926, 1928-1930, 1932, and 1935).

For years with WDR records (1920-1921, 1923, 1927, 1931, 1933-1934, 1936-1937), the total canal loss is the minimum of 40% and the river headgate ("RHG") diversion minus the farm headgate ("FHG") delivery divided by the RHG diversion. However, in all years, the canal loss is equal to the minimum 40%. For years with WDR records, the waste is computed as a residual (RHG diversion minus the canal loss). The waste residual volume is used to compute a waste percent (waste residual divided by RHG diversion) that is used in the EPCWID (El Paso Valley) annual CFB Model.

2.4.1 Incidental Canal Loss and Canal Seepage

The incidental canal loss is computed based on a user specified a percentage of the total canal loss and is set at 6%.

2.5 Maximum On-Farm Irrigation Efficiency ("MFE")

The MFE is a user-specified percent for each annual CFB Model. The MFE does not vary from year-to year. The MFE is currently set at 68% for all irrigation units.

2.6 On-Farm Loss Split

The surface runoff percentage is a user-specified percent for each annual CFB Model that does not vary from year-to year. The surface runoff percentage is currently set at the 6% for all irrigation units. The deep percolation percent is computed as one minus the surface runoff percent (94%).

2.7 Soil Moisture Reservoir

The soil moisture reservoir (inches) for the annual Hueco CFB Models are set equal to the values used in the monthly CFB Models.

2.8 Ground Water Pumping

There is no ground water pumping for irrigation supply on the Hueco lands from 1903 – 1937. However, the structure to simulate the supplemental and primary pumping has been added to the annual Hueco CFB Models.

Hydrologic and Water Quality Models: Performance Measures and Evaluation Criteria

Moriasi et al. (2015)

HYDROLOGIC AND WATER QUALITY MODELS: PERFORMANCE MEASURES AND EVALUATION CRITERIA

D. N. Moriasi, M. W. Gitau, N. Pai, P. Daggupati

ABSTRACT. *Performance measures (PMs) and corresponding performance evaluation criteria (PEC) are important aspects of calibrating and validating hydrologic and water quality models and should be updated with advances in modeling science. We synthesized PMs and PEC from a previous special collection, performed a meta-analysis of performance data reported in recent peer-reviewed literature for three widely published watershed-scale models (SWAT, HSPF, WARMF), and one field-scale model (ADAPT), and provided guidelines for model performance evaluation. Based on the synthesis, meta-analysis, and personal modeling experiences, we recommend coefficient of determination (R^2; in conjunction with gradient and intercept of the corresponding regression line), Nash Sutcliffe efficiency (NSE), index of agreement (d), root mean square error (RMSE; alongside the ratio of RMSE and standard deviation of measured data, RSR), percent bias (PBIAS), and several graphical PMs to evaluate model performance. We recommend that model performance can be judged "satisfactory" for flow simulations if monthly $R^2 > 0.70$ and $d > 0.75$ for field-scale models, and daily, monthly, or annual $R^2 > 0.60$, $NSE > 0.50$, and $PBIAS \le \pm 15\%$ for watershed-scale models. Model performance at the watershed scale can be evaluated as "satisfactory" if monthly $R^2 > 0.40$ and $NSE > 0.45$ and daily, monthly, or annual $PBIAS \le \pm 20\%$ for sediment; monthly $R^2 > 0.40$ and $NSE > 0.35$ and daily, monthly, or annual $PBIAS \le \pm 30\%$ for phosphorus (P); and monthly $R^2 > 0.30$ and $NSE > 0.35$ and daily, monthly, or annual $PBIAS \le \pm 30\%$ for nitrogen (N). For RSR, we recommend that previously published PEC be used as detailed in this article. We also recommend that these PEC be used primarily for the four models for which there were adequate data, and used only with caution for other models. These PEC can be adjusted within acceptable bounds based on additional considerations, such as quality and quantity of available measured data, spatial and temporal scales, and project scope and magnitude, and updated based on the framework presented herein. This initial meta-analysis sets the stage for more comprehensive meta-analysis to revise PEC as new PMs and more data become available.*

Keywords. *Guidelines, Model calibration and validation, Performance measures and evaluation criteria.*

Hydrologic and water quality (H/WQ) models are increasingly being used to determine the impacts of land management, land use, climate, and conservation practices on water resources, ecology, and water-related ecosystem services. Hydrologic cycle components and fate and transport of sediments and chemicals are examples of complex systems comprised of many processes that can be simulated using H/WQ models. A majority of H/WQ models require some degree of calibration to reduce the uncertainty of predictions (Engel et al., 2007; USEPA, 2009). Calibration is the process of adjusting input parameter values and initial or boundary conditions within reasonable ranges until the simulated results closely match the observed variables (Zeckoski et al., 2015). Calibration requires the examination of accuracy of outputs and process simulation (Sorooshian, 1983) to ensure adequate watershed and scenario representation. This requires use of model performance measures (PMs) and the corresponding performance evaluation criteria (PEC). Throughout this article, the term "PMs" refers to the statistical and graphical methods used during model calibration and validation, "performance data" refers to the reported values of each of the statistical PMs (e.g., 0.5 for NSE), and "PEC" refers to model performance qualitative ratings (e.g., very good, good, satisfactory, or unsatisfactory) with the corresponding quantitative thresholds for the statistical PMs of interest (e.g., NSE, PBIAS, or R^2). Validation is the process by which a calibrated model is shown to be capable of reproducing a set of field observations or predicting future conditions without further adjustment to the calibrated parameters (Zheng et al., 2012).

Modelers have used different PMs, including statistical, graphical, or a combination of both. For example, Herr and Chen (2012) preferred the use of absolute and relative error, while Huth et al. (2012) recommended and used a variety of measures, including Nash-Sutcliffe efficiency (NSE; Nash and Sutcliffe, 1970) and the ratio of root mean square error (RMSE) and standard deviation of measured data (RSR; Moriasi et al., 2007). Commonly used graphical PMs include time series plots (e.g., van der Keur et al., 2001; Mutiti and Levy, 2010; Palosuo et al., 2011; Arnold et al., 2012; Herr and Chen, 2012; Huth et al., 2012), scatter plots (e.g., Palosuo et al., 2011; Herr and Chen, 2012), cumulative charts (e.g., Herr and Chen, 2012), and contour maps (e.g., Zheng et al., 2012).

Nevertheless, the use of both graphical and statistical PMs is essential for robust model performance evaluation (Biondi et al., 2012; Bennett et al., 2013; Harmel et al., 2014; Daggupati et al., 2015a). For instance, measures such as the NSE are insensitive to systematic errors and yield good model performance even if low values are poorly fitted (Krause et al., 2005; Ritter and Muñoz-Carpena, 2013; Pfannerstill et al., 2014). In such cases, graphical PMs provide supplementary evidence as to where (e.g., in the time series, magnitude of event, depth, etc.) the model is not performing adequately. In addition, pre-inspection of graphical output likely minimizes equifinality (or parameter non-uniqueness), a situation in which a variety of parameter sets can yield acceptable model performance (Beven and Freer, 2001; Doherty and Johnston, 2003). This is achieved by allowing identification of parameter sets that provide better process simulation, thereby reducing the number of possible parameter sets that yield acceptable model performance. Recent works indicate that the intended use of the model could serve as an important factor in the selection of PMs and PEC (Finsterle et al., 2012; Harmel et al., 2014).

Past literature on model PMs includes Willmott (1984), Loague and Green (1991), ASCE (1993), Refsgaard (1997), Gupta et al. (1998), Legates and McCabe (1999), Santhi et al. (2001), Krause (2005), McCuen et al. (2006), Engel et al. (2007), and Moriasi et al. (2007). With respect to PEC, several studies have provided a summary of ranges of values for use in assessing model performance (Popov, 1979; Ramanarayanan et al., 1997; Gassman et al., 2007; Moriasi et al., 2007; Douglas-Mankin et al., 2010; Tuppad et al., 2011; Ritter and Muñoz-Carpena, 2013). The use of PEC provides objective indications of the adequacy of model performance, hence affording greater credibility to the modeling work (Duda et al., 2012). General PEC help model users and decision makers estimate model calibration and validation accuracy, usability for their specific application, and uncertainty or reliability of model predictions (Duda et al., 2012). It is also important to set PEC before beginning model evaluation (ASCE, 1993; USEPA, 2002; Engel, 2007; Moriasi et al., 2007).

Selection and use of PEC also varies by study and by model (Santhi et al., 2001; Van Liew et al., 2007; Parajuli et al., 2009; Benett et al., 2013, Daggupati et al., 2014; Harmel et al., 2014). This could result in inconsistent model evaluation, making it difficult to provide a benchmark for further model improvements. Moriasi et al. (2007) provided guidance to facilitate a more consistent and structured approach for model performance evaluation. However, the scope of the guidelines provided by Moriasi et al. (2007) was limited to NSE, percent bias (PBIAS; Gupta et al., 1999), and RSR for stream flow, sediment, and nutrient (N and P) simulations at a monthly temporal scale and watershed spatial scale. Different PMs can have differing ranges of conditions for which they are best suited (Krause et al., 2005; Gupta et al., 2009; Westerberg et al., 2011; Pushpalatha et al., 2012). Just as there are differences in PMs, there are also differences in the PEC for each measure. In addition, models perform differently for different simulated response outputs and, perhaps, at different temporal and spatial scales (Westerberg et al., 2011; Biondi et al., 2012), which may require different PEC. For example, regions with a shallow water table (e.g., south Florida) experience rapid water table rise within 12 hours of rainfall or irrigation input (Jaber et al., 2006; Hendricks et al., 2013). Hendricks et al. (2013) evaluated a daily temporal scale model for simulating water table responses in a shallow water table region of Florida and concluded that a daily temporal scale was a fundamental limitation because the hydrologic response time was less than 12 hours. Therefore, there is need to explore how different models perform under different conditions using different PMs to help determine appropriate PEC. Further, Moriasi et al. (2007) stated that "as new and improved methods and information are developed, the recommended guidelines should be updated to reflect these developments."

Recently, Biondi et al. (2012), Ritter and Muñoz-Carpena (2013), Moriasi et al. (2012), Pushpalatha et al. (2012), Bennett et al. (2013), Black et al. (2014), and Harmel et al. (2014) focused on various aspects of performance of H/WQ models. Biondi et al. (2012) performed a literature review and provided general model validation guidelines that cover several topics discussed in this special collection. Black et al. (2014) provided general guidance on the implementation and application of water resource management models focused on scenario analysis. Bennett et al. (2013) reviewed and provided methods available across different fields for describing the performance of environmental models focusing on model PMs. Pushpalatha et al. (2012) analyzed several forms of NSE to determine the form that was suitable for flows. Ritter and Muñoz-Carpena (2013) presented a unified framework for determining model PEC in a statistically rigorous way and for the evaluation of bias, outliers, and repeated data focused on RMSE and NSE. Harmel et al. (2014) reviewed literature and recommended a broad methodology that takes into account intended use to establish model performance expectations. The methodology provides a brief summary of several topics, including model valuation, interpretation, and communication of model results.

Moriasi et al. (2012) summarized the results of 25 H/WQ models in a special collection of 22 articles, each focusing on individual model calibration and validation strategies. The special collection provided a good source of model-specific calibration and validation examples, performance evaluation examples, and references. However, there is need for consistent model calibration and validation guidelines (Moriasi et al., 2012), including PMs and PEC.

Recognizing the good work done by others, in this article we: (1) synthesize the special collection articles (Moriasi et al., 2012) with respect to PMs and PEC; (2) perform a meta-analysis of performance data as reported in peer-reviewed literature by considering the effects of calibration and validation periods, simulated components, and spatial and temporal scales; and (3) establish guidelines for model performance evaluation based on information from the synthesis (objective 1) and meta-analysis (objective 2). Further, we present an example case study illustrating the application of our recommendations in model calibration and validation.

In summary, this article is one of nine topic-specific articles in a special collection whose main goal is to provide recommendations, which together with information from other literature will be used to develop model calibration and validation engineering practices for H/WQ models. These articles extensively cover critical issues related to the calibration and validation of H/WQ models. This article focuses on model PMs and the corresponding PEC related to models in the Moriasi et al. (2012) special collection and provides a more rigorous framework than Moriasi et al. (2007, 2012) for determining PEC, involving a meta-analysis of the performance data collected in this study and using the results to guide PEC development.

METHODS

SYNTHESIS OF PERFORMANCE MEASURES AND EVALUATION CRITERIA

As a starting point, the articles in the Moriasi et al. (2012) special collection were reviewed to determine the statistical and graphical PMs used for each of the models. The models in the special collection were grouped into three spatial categories (point to plot, field, and watershed; table 1). PMs and PEC reported outside of the special collection were helpful in broadening the outlook on PEC and providing additional materials useful for establishing guidelines. Commonly used PMs and PEC within and outside the special collection (Moriasi et al., 2012) for each model were recorded for in-depth analyses.

Although there are several ways in which statistical PMs can be categorized (Moriasi et al., 2007; Bennett et al., 2013), in this article statistical PMs are discussed and divided into three broad categories: (1) standard regression, (2) dimensionless, and (3) error index based on Moriasi et al. (2007). Standard regression measures determine the strength of the linear relationship between simulated and measured data. Dimensionless measures provide a relative model evaluation assessment, and error index measures quantify the deviation in the units of the data of interest (Legates and McCabe, 1999). Graphical PMs are divided into two categories (direct and derived comparison), and information about the strengths and weaknesses of each of the measures was obtained from the literature. In this article, we define direct comparison graphical PMs as graphical PMs in which original measured and simulated data are compared with each other, for instance, with time series graphs. Derived graphical PMs are those in which meas-

Table 1. Models in the Moriasi et al. (2012) special collection grouped by spatial scale.

Model	Simulated Processes (Components)	Reference
Point to plot scale		
COUPMODEL	Hydrology, N, carbon, plant growth, heat, tracer, chloride	Jansson (2012)
HYDRUS	Water flow, solute transport, heat transfer, carbon dioxide	Šimůnek et al. (2012)
MACRO	Macropore flow, pesticides	Jarvis and Larsbo (2012)
MT3DMS	Multispecies solute transport, groundwater	Zheng et al. (2012)
SHAW	Hydrology, heat transfer	Flerchinger et al. (2012)
STANMOD	Solute transport in soils and groundwater	van Genuchten et al. (2012)
SWIM3	Water and solute movement	Huth et al. (2012)
TOUGH2	Multiphase, multicomponent fluids in porous and fractured geologic media	Finsterle et al. (2012)
VS2DI	Water, solute, heat transport	Healy and Essaid (2012)
Field scale		
ADAPT	Hydrology, erosion, nutrients, pesticides, subsurface tile drainage	Gowda et al. (2012)
CREAMS/GLEAMS	Hydrology, erosion, pesticides, sediments, nutrients, plant growth	Knisel and Douglas-Mankin (2012)
DAISY	Water, snowmelt, carbon cycle, energy balance, N cycle, crop production, pesticides	Hansen et al. (2012)
DRAINMOD	Hydrology (water table depth, tile flow, surface runoff, depth of irrigation water applied, wetland hydrology), plant growth (crop yield)	Skaggs et al. (2012
EPIC/APEX	Hydrology (surface runoff, stream flow, tile flow), plant growth, erosion, sediments, nutrients, pesticides	Wang et al. (2012)
RZWQM2	Hydrology, plant growth, nutrients, pesticides	Ma et al. (2012)
WEPP Hillslope	Hydrology, soil erosion	Flanagan et al. (2012)
Watershed scale		
BASINS/HSPF	Hydrology, snowmelt, pollutant loadings, erosion, fate and transport	Duda et al. (2012)
KINEROS2/AGWA	Runoff, erosion, sediments	Goodrich et al. (2012)
MIKE-SHE	Surface and subsurface water dynamics, interception, evapotranspiration, overland flow, channel flow, unsaturated flow, saturated zone flow, water levels, surface and groundwater quality	Jaber and Shukla (2012)
SWAT	Hydrology, plant growth, sediments, nutrients, pesticides	Arnold et al. (2012)
WAM	Hydrology, sediments, nutrients	Bottcher et al. (2012)
WARMF	Hydrology, sediments, nutrients, acid mine, carbon, bacteria	Herr and Chen (2012)
WEPP Watershed	Hydrology, soil erosion	Flanagan et al. (2012)

ured or simulated data are first transformed into another form before they are displayed in a comparative graph, for example, frequency duration curves.

A comparative analysis of the reported PMs was performed to evaluate (1) how they compare across the models, (2) their advantages and disadvantages, and (3) their usability (ease of and suitability for use) from a user or non-developer perspective. Additional considerations for PMs included their suitability for event-based vs. continuous models and their use with missing and/or discrete observed data. Based on this analysis, recommendations are made for suitable PMs.

META-ANALYSIS OF PERFORMANCE DATA

A statistical meta-analysis was performed on the model performance data to guide the development of the PEC. Simply stated, a meta-analysis (Glass, 1976; Hunter et al., 1982; Hunt, 1997; Lyons, 1998; among others) is the accumulation and analysis of data from separate but similar studies for the purpose of obtaining insights from the pooled data that are not discernible from the individual studies. The methodology provides an avenue for bringing together information from various related studies in search of common patterns and conclusions. It can also be used to reconcile data from disparate studies. Since its inception in the 1970s, meta-analysis has been applied successfully in various fields, including medical research and social studies (Egger and Smith, 1997; Lyons, 1998; Bland, 2000). The methodology has also been used successfully in natural resources and environmental systems for the development of a Best Management Practice (BMP) tool (Gitau et al., 2005).

The accumulation of data from existing studies is the most involved part of a meta-analysis, as it requires considerable attention to some key considerations, as described in ensuing subsections.

Kinds of Articles to Include

It is necessary that articles be relevant to the study at hand (Light and Smith, 1971; Hunt, 1997) and that the articles contain the information needed to achieve study goals. As materials may be subject to re-interpretation, it is preferable that the articles contain original material and include a detailed account of the study. Further, given a common tendency toward selecting articles that favor an author's viewpoint and/or that align with prevailing opinion (Egger and Smith, 1997), it is important that article selection follows an objective procedure. For example, in this article, the articles included are primary sources that provided performance data for the various PMs. Additional criteria included the presence of details such as models used, evaluation time step, components evaluated, and whether data reported were for calibration or validation.

Whether or Not to Use Only Published Material

Generally, published material is deemed to have more reliable data and is afforded more credibility than unpublished material. However, published material is often preferential in nature, favoring research works based on reported significance (Lipsey and Wilson, 2001). For example, in regard to model performance, articles reporting higher values of NSE may be preferentially published, whereas those with lower values (albeit with better parameter representations) may take a while longer or may not be published at all. Including only published material may result in a publication bias (Light and Smith, 1971; Hunter et al., 1982; Light and Pillemer, 1984; Bland, 2000); thus, we recommend that both published and unpublished material be included. The challenge lies in being able to find unpublished information, as this is not generally available. Thus, the dataset developed for this article only contains data from published material (peer-reviewed journal articles after 1990).

Rejection of Articles on the Basis of Perceived Inadequacies in the Methodology

Another important consideration is the determination of article suitability for inclusion based on methodologies used. This is especially so for unpublished information, as a work may be unpublished due to unsuitable methodologies. However, it is important to note that flaws can be identified in almost any article (Hunter et al., 1982; Lipsey and Wilson, 2001) given that opinions tend to differ among researchers. The use of methodology as a basis for article inclusion would thus introduce elements of subjectivity into the analysis (Light and Smith, 1971) and would result in a reduced dataset (Glass, 1976; Hunter et al., 1982), which would then impact the analysis. In this study, no judgements were made as to the adequacy or inadequacy of the methodologies used once an article was deemed suitable for inclusion based on study goals.

Amount of Data Necessary for Analyses

The ideal case would be to have all existing data; in this case, the details and results of all studies in which model calibration and validation have been conducted and performance values have been reported. However, this is generally not practical, due to limited access to unpublished material, if nothing else, and thus the need for a representative sample arises. In addition, it is necessary to consider the study goals. For example, in this article, the goal was to capture recent advances in modeling (in the 1990s and later) for commonly used H/WQ models published in a recent special collection (Moriasi et al., 2012) when establishing performance criteria. For this work, the target was to review a minimum of 20 articles (outside the Moriasi et al. (2012) special collection) per model for the most commonly simulated output responses (flow, sediment, and nutrients) to be reviewed. To enable meta-analysis, each reported entry of performance data was extracted and tabulated along with size of the study area (supplemental material tables S1-1 through S1-22, available at http://bit.ly/NRES_SW10715). Exceptions were permitted for models for which the available peer-reviewed articles numbered less than 20, in which case all available articles were reviewed. Data on stream flow, surface runoff, base flow, and tile flow model performance values were combined as appropriate and referred to as flow for the watershed-scale and ADAPT models to ensure that there were sufficient data for analyses. Where stream flow was the only component used in the analysis and/or discussion, the term "stream flow" was used to distinguish it from the combined flow component. Data were commonly reported in the literature at annual, monthly, and daily temporal scales for watershed-scale models and at a monthly temporal scale for field-scale models. In addition, there was a substantial amount of seasonal data associated with PBIAS.

Handling of Extreme Values

Values showing up as extreme values, once all data are assembled, may reflect extreme site or study characteristics; thus, their exclusion would mask the existence of extremes. Therefore, extreme values such as values of other PMs for studies in which there were negative NSE values were not excluded from the primary analysis. However, negative NSE values were not included in criteria development, as such values represent unacceptable model performance. Further description is provided under the "Meta-Analysis of Performance Data" subheading within the "Results and Discussion" section.

Data Analyses

Once all data are assembled, the most basic analysis involves determining an average for each data component (Hunter et al., 1982; Light and Pillimer, 1984; Hunt, 1997), for example, an average of all NSE values. More detailed approaches involve the computation of standardized metrics to account for differences in the amounts of data among studies (Light and Pillimer, 1984; Lipsey and Wilson, 2001). In either case, this would mask the variability in the data, so more in-depth analysis allowing the examination of factors that could affect results (Hunter et al., 1982; Light and Pillimer, 1984; Hunt, 1997) and extraction of other pertinent information are necessary.

In this study, descriptive statistics such as mean, median, minimum, and maximum were computed for the performance data, and the associated distributions were plotted in order to make a determination on subsequent analysis. Following these preliminary diagnostics, significant differences in reported values were determined based on (1) calibration or validation; (2) scale (specifically watershed-scale studies based on Hydrologic Unit Code (HUC; https://pubs.er.usgs.gov/publication/ofr84708; direct comparisons were not made between watershed and field scales due to the large difference in available data); and (3) model components (e.g., flow, sediment, and nutrients). The analysis was conducted using the median test, a non-parametric (typically distribution-free) test based on median rank scores (SAS, 2007; Sheskin, 2003; Brown and Mood, 1951). The test considers all observations and ranks them as 0 or 1 based on their location around (above or below) the median. Resulting rank scores are then used for the comparisons based on the chi-square statistic and associated probabilities. In addition, the performance data were plotted on a common axis to provide a visual comparison. All analyses were carried out using JMP statistical software (SAS, 2008).

Development of Guidelines for Model Performance Evaluation

The median test on reported performance data was used to determine whether separate PEC were needed for calibration and validation periods, spatial and temporal scales, and for different simulated response outputs. Following the median test, thresholds for model PEC ratings were established by computing percentiles or quartiles of model PM data collected from peer-reviewed articles outside the Moriasi et al. (2012) special collection. The thresholds obtained for the defined ratings formed the initial PEC, which along with the results of the synthesis of the PEC and the modeling experience of the authors were used to develop final PEC guidelines for identified separate categories. A similar approach was used by USEPA (2010) as part of an evaluation of the potential benefits of numeric nutrient criteria for Florida's flowing waters. The guidelines are in the form of recommended PMs and PEC. Brief descriptions are provided for (1) the importance of following proper calibration and validation procedures (Zeckoski et al., 2015; Arnold et al., 2015; Baffaut et al., 2015; Malone et al., 2015; Daggupati et al., 2015b; Guzman et al., 2015; and Yuan et al., 2015) prior to using these general guidelines; (2) additional considerations for adjusting the general recommendations because of the variety of modeling applications; and (3) a framework for determining recommended model PMs and their corresponding PEC.

Results and Discussion

Synthesis of Performance Measures and Evaluation Criteria

The most commonly used graphical PMs in the special collection articles were time series charts (table 2; e.g., WARMF, DAISY, VS2DI, SWIM3, and SWAT). Other graphical PMs included scatter plots (e.g., APEX/EPIC, CREAMS/GLEAMS, DAISY, WARMF, and SWAT), cumulative frequency curves (e.g., WARMF, SWAT), contour maps (e.g., MT3DMS), depth profile plots (e.g., SWIM3), thermographs in which heat is used as a surrogate for water movement (e.g., VS2DI), and bar charts (e.g., EPIC/APEX). Thermographs are quite common in soil/water-solute transport applications.

The most commonly used statistical PMs were NSE, RMSE (also called root mean square deviation, RMSD), and R^2 (table 2). Other reported statistical PMs included *d* (Willmott, 1981), PBIAS (Gupta et al., 1999), mean absolute error, R, absolute error, relative error, standard error of estimate, non-parametric tests, RSR (Moriasi et al., 2007), 95% confidence intervals (to account for uncertainty, mean, and standard deviation), autocorrelation, and cross-correlation (table 2). Brief descriptions as well as discussions of the strengths, weaknesses, and usage of the commonly used measures are presented in ensuing subsections. The abbreviations of the models in the Moriasi et al. (2012) special collection are provided in the Appendix, while the statistical PMs and associated equations are provided in table 5. Detailed accounts of these and other measures can be obtained from model-specific articles and in the literature (e.g., Wilmott, 1984; Legates and McCabe, 1999; Krause et al., 2005; Moriasi et al., 2007; Ritter and Muñoz-Carpena, 2013; Bennett et al., 2013; Harmel et al., 2014).

Of the models within the Moriasi et al. (2012) special collection, only a few provided PEC (table 3), including

Table 2. Summary of performance measures and evaluation criteria for H/WQ models in the Moriasi et al. (2012) special collection.

[a] NSE = Nash Sutcliffe efficiency/coefficient, R^2 = coefficient of determination, RMSE = root mean square error/deviation, *d* = index of agreement, PBIAS = percent bias/deviation. "Other" includes root mean square error to standard deviation ratio, linear or weighted correlation coefficient, mean error, mean absolute error, standard error of estimate, 95% confidence interval, comparison between observed and predicted means and standard deviations, mean and variance of weighted residuals, autocorrelation, cross-correlation, nonparametric tests, t-tests, and objective functions.
[b] n.p. = not provided and user-defined.
[c] CFC = cumulative frequency curves.

BASINS/HSPF (Duda et al., 2012), DRAINMOD (Skaggs et al., 2012), EPIC/APEX (Wang et al., 2012), KINEROS/AGWA (Goodrich et al., 2012), RZWQM2 (Ma et al., 2012), and WARMF (Herr and Chen, 2012). PEC from Moriasi et al. (2007) were cited for SWAT (Arnold et al., 2012), SWIM3 (Huth et al., 2012), and WEPP (Flanagan et al., 2012). With the exception of SWIM3 (Huth et al., 2012), all point and plot scale models (table 3) employed user-defined objective function thresholds with autocalibration algorithms (Moriasi et al., 2012). The MIKE-SHE (Jaber and Shukla, 2012) and WAM (Bottcher et al., 2012) articles do not provide any PEC.

Graphical Performance Measures

Graphical PMs provide an important complementary tool for modelers to support the calibration and validation of H/WQ models (Daggupati et al., 2015a). Graphical PMs allow visual comparison of simulated and measured output response data, help identify model bias, identify differences in timing and magnitude of peaks (e.g., peak flows) and shape of recession curves, incorporate measurement (Harmel and Smith, 2007) and model (Shirmohammadi et al., 2006) uncertainty, and illustrate how well the model reproduces the frequency of measured daily values (Pfannerstill et al., 2014). The disadvantage of graphical PMs is that model performance can be obtained only qualitatively through them. In addition, graphical PMs can easily be manipulated to look good by scaling.

Table 4 lists a variety of graphical PMs used commonly to support and present results of H/WQ model calibration and validation. The graphical PMs are grouped into two broad categories (direct and derived) to enable users to determine appropriate graphical PMs for their study.

The spatial and temporal scale of simulation could be used to determine graphical performance measures that will be effective in communicating model performance to end users. The most effective graphical measures are ones that highlight specific predictive capabilities of the model. For shorter-term modeling (<1 year), a time series plot can be an effective tool. The performance of models for longer-duration datasets (≥10 years of daily data) is better understood by using either a scatter plot or a duration curve. For instance, when Duda et al. (2012) presented the daily-scale five-year calibration results for an HSPF model application, they provided both a time series graph and a duration curve. The time series graph, which contained approximately 1825 data points, gave the impression that the model sometimes overestimated or underestimated peak flows, depending on the peak. This presented a confusing picture of model performance. The authors then presented the same data in the form of a flow duration curve. The flow duration curve not only indicated that, in general, the model-simulated values were close to the observed values (similar to what was understood from the time series plot), but it also showed that the model overestimated higher flows and underestimated medium and lower flows during the validation period. Thus, the duration curve was a more effective tool for understanding and communicating daily model

Table 3. Reported performance evaluation criteria for models in the Moriasi et al. (2012) special collection.

Model (and Reference)	Response Output	Performance Evaluation Criteria				
BASINS/HSPF (Duda et al., 2012)		Difference between Simulated and Recorded Values (%)				
		Very Good	Good	Fair		
	Hydrology/flow	<10	10 to 15	15 to 25		
	Sediment	<20	20 to 30	30 to 45		
	Water temperature	<7	8 to 12	13 to 18		
	Water quality/nutrients	<15	15 to 25	25 to 35		
	Pesticides/toxics	<20	20 to 30	30 to 40		
		Statistical Evaluation Criteria				
	Hydrology/flow	Statistic	Very Good	Good	Fair	Poor
	Daily	R	≥0.89[a]	≥0.84	≥0.77	<0.77
	Monthly	R	≥0.92	≥0.87	≥0.81	<0.81
	Daily	R^2	≥0.80	≥0.70	≥0.60	<0.60
	Monthly	R^2	≥0.85	≥0.75	≥0.65	<0.65
DRAINMOD (Skaggs et al., 2012)		Statistical Evaluation Criteria				
		Statistic	Excellent	Good	Acceptable	
	Water table depth (daily)	MAE (cm)	<10	<15	<20	
		NSE	>0.75	>0.60	>0.40	
	Drainage volume ($cm^3\ cm^{-2}$)					
	Daily	NSE	>0.75	>0.60	>0.40	
	Monthly	NSE	>0.80	>0.70	>0.50	
	Annual	NSE	>0.85	>0.75	>0.60	
		NPE	<5%	<15%	<25%	
EPIC/APEX (Wang et al., 2012)		Satisfactory Calibration Criteria				
		R^2	NSE	PBIAS	Mean and SD	Graphical
	Runoff or water yield	≥0.60	≥0.55	Within 20%	-	Simulated time-series flow captures the trend or pattern of measured data.
	Crop yield	≥0.60	-	Within 25%	-	Simulated time-series crop yield captures the trend or pattern of measured data.
	Sediment yield	≥0.60	≥0.50	Within 35%	Simulated mean and SD compare closely with measured values	Simulated time-series sediment yield captures the trend or pattern of measured data.
	Nutrient loss	≥0.60	≥0.50	Within 50%	-	Simulated time-series nutrient loss captures the trend or pattern of measured data.
KINEROS/AGWA (Goodrich et al., 2012)		Acceptable Model Performance				
	Runoff, erosion, sediments	Simulated values within 30% of observed (Al-Qurashi et al., 2008)				
RZWQM2 (Ma et al., 2012)		Acceptable Model Simulation				
		R^2	NSE	*d*	PBIAS	
	Hydrology, plant growth, nutrients, pesticides	≥0.80	≥0.70	≥0.70	Within 15%	
WARMF (Herr and Chen, 2012)		Good Model Performance				
	Hydrology/flow	<20% absolute error				
	Nutrients	<30% absolute error				
	Phytoplankton and suspended sediment	<50% absolute error				

[a] Values estimated from figure 4 (Duda et al., 2012).

performance for their case study. The effectiveness of using a duration curve is also demonstrated in a case study presented later in this article.

As discussed in table 4, certain derived graphical PMs, such as cumulative plots and maps, can provide a misleading picture of model performance. For instance, a combination of cumulative and daily time series plot was used by Bottcher et al. (2012) to present results of the WAM model (fig. 1). The presentation of these two plots was essential because the cumulative plot gives the impression that the model overpredicts initially and underpredicts in the latter part of simulation but has reasonable overall performance. On the other hand, the time series plot shows that certain important flow peaks were completed missed. The time series plot allows the modeler to find temporal mismatches that could go unnoticed by using only a cumulative plot.

Maps are also effective tools for presenting key results and meeting the objectives of watershed models. For example, to build confidence in an uncalibrated SWAT model, Srinivasan et al. (2010) used maps to show that SWAT-simulated annual corn and soybean yields for each subbasin were consistent with USDA-NASS estimates. Pai et al. (2011) and Daggupati et al. (2011) used maps of sediment, total P, and nitrate-N outputs to prioritize subwatersheds and fields in SWAT model applications in Arkansas and Kansas. Such maps could be used to assess spatial model performance.

STATISTICAL PERFORMANCE MEASURES

Statistical PMs are widely used to quantify the performance of H/WQ models in describing the "closeness" of the simulated behavior to observations. Table 5 summarizes commonly used statistical PMs based on the Moriasi et al. (2012) special collection, along with their demonstrated advantages/disadvantages, ranges, optimal values, and the equations used to compute them. Harmel et al. (2014), Bennett et al. (2013), Krause et al. (2005), and Coffey (2004) also provide a comprehensive list of statistical PMs. Although there are different ways to categorize PMs (Moriasi et al., 2007; Bennett et al., 2013), the PMs in this article

Table 4. Summary of graphical performance measures for H/WQ model calibration and validation.

	Purpose	Advantages/Disadvantages
Direct comparison		
Scatter plots	Compare observed and simulated data with no dependent variable. A least square regression line can be fitted to observe deviation from the 1:1 line.	**Advantages:** Divergence from the 1:1 line provides a visual understanding of the underlying behavior of the model, including any bias or systematic variance. **Disadvantages:** Data points clumped in the low intensity, high frequency range and few in the high intensity, low frequency range can artificially make a model's performance look good.
Time-series plots	Compare observed and simulated data with time as a dependent variable.	**Advantages:** Helps inspect and support troubleshooting event-specific prediction issues, including mismatches in magnitude of peaks and shape of recession curve, and outliers. Time series plots can also guide selection of parameters to be used for calibration. **Disadvantages:** Time series plots become cluttered with too many data points.
Derived comparison		
Cumulative plots	Compare cumulative observed and simulated values with time as dependent variable.	**Advantages:** Allows identification of any systematic temporal divergence between observed and simulated values. **Disadvantages:** Cumulative plots may still converge, with major temporal mismatches. They should be used as a preliminary model performance-screening tool.
Flow and load duration curves	Compare observed and simulated values with probability as a dependent variable.	**Advantages:** Provides insight into model performance over different flow/load regimes (i.e., low, medium, high; Pfannerstill et al., 2014). **Disadvantages:** Needs a larger number of data points to derive meaningful conclusions. Duration curves are most useful for long-term monthly, daily, or subdaily calibrations.
Maps	Map showing the output of interest at the desired spatial scale. Examples include showing annual sediment loss for each subwatershed.	**Advantages:** Useful for presenting field-scale to watershed-scale model results for understanding the spatial performance of the model. Pollutant hotspots within a watershed can be quickly identified using color-codes. **Disadvantages:** Choices of color-coding and grouping within a map can sometimes be misleading. For example, red colored areas may or may not represent critical areas depending on actual values plotted.

are grouped as standard regression, dimensionless, and error index, as discussed below.

Standard Regression

Pearson's correlation coefficient (r) and coefficient of determination (R^2) describe the degree of collinearity between simulated and measured data. The correlation coefficient is an index that is used to investigate the degree of linear relationship between observed and simulated data. R^2 is the squared value of r, although it can also be expressed as the squared ratio between the covariance and the multiplied standard deviations of the observed and predicted values (Krause et al., 2005).

Dimensionless

The Nash-Sutcliffe efficiency (NSE) is a normalized statistic that determines the relative magnitude of the residual variance ("noise") compared to the measured data variance ("information"; Nash and Sutcliffe, 1970). NSE indicates how well the plot of observed versus simulated data fits the 1:1 line. Many studies (e.g., Santhi et al., 2001; Vazquez-Amabile and Engel, 2005; Reungsang et al., 2010; Pai et al., 2011; Douglas-Mankin et al., 2013) have used NSE to evaluate model performances for various output responses (e.g., flow, sediment, N, P, crop yields, etc.) using different models (MIKE-SHE, ADAPT, SWAT, WARMF, HSPF, etc.).

The index of agreement (*d*) was developed by Willmott (1981) as a standardized measure of the degree of model prediction error. The index of agreement represents the ratio between the mean square error and the "potential error" (Willmott, 1984). The potential error (denominator in index of agreement equation in table 5) represents the largest value that the squared difference of each pair can attain. The index of agreement can detect additive and proportional differences in the observed and simulated means and variances.

Error Index

The root mean square error (RMSE) is the square root of mean square error (MSE). The MSE is also known as standard error of the estimate in regression analysis. The RMSE is measured in the same units as the model output response of interest and is representative of the size of a typical error.

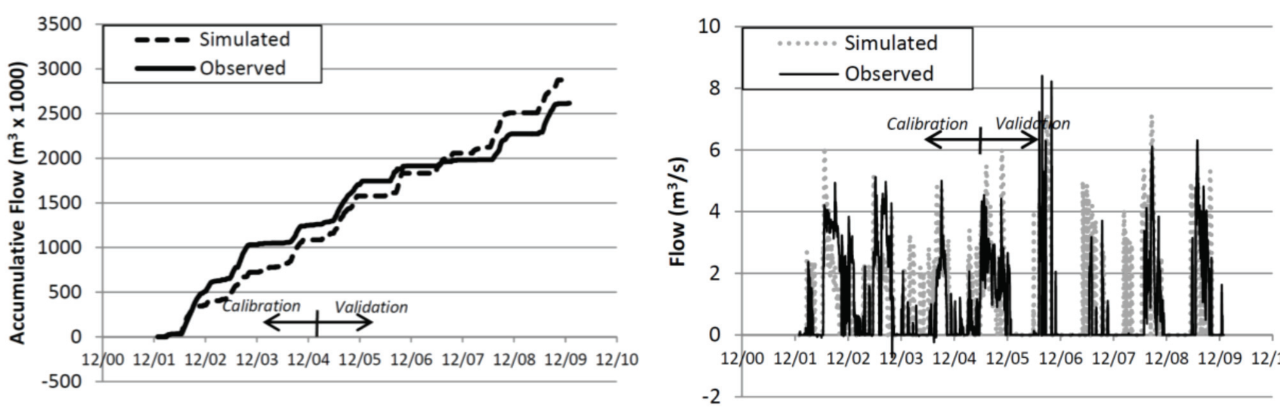

Figure 1. Calibrated daily flow using the WAM model (reproduced from Bottcher et al., 2012).

Table 5. Equations, ranges, optimal values, and advantages and disadvantages for statistical performance measures in the Moriasi et al. (2012) special collection (*O* and *P* are observed and predicted values, respectively).

Statistic	Equation	Range	Optimal Value	Advantages/Disadvantages
r	$\frac{\sum_{i=1}^{n}\left(O_i-\bar{O}\right)(P_i-\bar{P})}{\sqrt{\sum_{i=1}^{n}\left(O_i-\bar{O}\right)^2}\sqrt{\sum_{i=1}^{n}\left(P_i-\bar{P}\right)^2}}$	-1.0 to 1.0	-1.0 (negative slope) or 1.0 (positive slope)	**Advantages:** R^2 and r are widely used in hydrological modeling studies, thus serving as a benchmark for performance evaluation. **Disadvantages:** R^2 and r are oversensitive to high extreme values (Krause et al., 2005) and insensitive to additive and proportional differences between model predictions and measured data (Legates and McCabe, 1999). **Notes:** We recommend that the regression line gradient and intercept be reported when R^2 is used as a performance measure. For a good agreement, the intercept should be close to zero and the gradient should be close to one (Krause et al., 2005).
R^2	$\left[\frac{\sum_{i=1}^{n}\left(O_i-\bar{O}\right)(P_i-\bar{P})}{\sqrt{\sum_{i=1}^{n}\left(O_i-\bar{O}\right)^2}\sqrt{\sum_{i=1}^{n}\left(P_i-\bar{P}\right)^2}}\right]^2$	0.0 to 1.0	1.0	
NSE	$1-\frac{\sum_{i=1}^{n}\left(O_i-P_i\right)^2}{\sum_{i=1}^{n}\left(O_i-\bar{O}\right)^2}$	-∞ to 1.0	1.0	**Advantages:** NSE is: (1) a quantitative measure conducive to development of PEC; (2) good for use with continuous long-term simulations and can be used to determine how well the model simulates trends for the output response of concern; (3) robust and can be used to evaluate model performance for several output responses (e.g., stream flow, sediments, nutrients, pesticides) and temporal scales; and (4) commonly used, which means that there is extensive information on reported values, which can be used for comparison purposes. Further, it can incorporate measurement uncertainty (Harmel and Smith, 2007; Harmel et al., 2010). **Disadvantages:** NSE cannot help identify model bias and cannot be used to identify differences in timing and magnitude of peak flows and shape of recession curves; in other words, it cannot be used for single-event simulations. **Notes:** NSE is sensitive to extreme values due to the squared differences (Krause et al., 2005). To overcome extreme-value cases and increase sensitivity to lower measured and simulated values, Krause et al. (2005) recommended the use of logarithmic and relative derivatives forms of NSE and *d*. In cases where the measured data are bi-modal with high and low distributions in the same study area, such as the measured flows in Cho and Olivera (2009), it is recommended that the two data categories be separated to avoid the bias toward simulation of lower values.
d	$1-\frac{\sum_{i=1}^{n}\left(O_i-P_i\right)^2}{\sum_{i=1}^{n}\left(\left\|P_i-\bar{O}\right\|+\left\|O_i-\bar{O}\right\|\right)^2}$	0.0 to 1.0	1.0	**Advantages:** The index of agreement (1) detects additive and proportional differences in the observed and simulated means and variances and (2) is widely used, and thus there is comprehensive information on reported values in the literature. **Disadvantages:** Overly sensitive to extreme values due to the squared differences (Legates and McCabe, 1999). High values of *d* were reported even for poor model fits (Krause et al., 2005). **Notes:** *d* should be evaluated based on the phenomenon studied, measurement accuracy, and the model employed. It can also be used as a substitute for R^2 to identify the degree to which model predictions are error-free (Legates and McCabe, 1999). Further, it can incorporate measurement uncertainty (Harmel and Smith, 2007; Harmel et al., 2010).
RMSE or RMSD	$\sqrt{\frac{1}{n}\sum_{i=1}^{n}\left(O_i-P_i\right)^2}$	0.0 to ∞	0.0	**Advantages:** RMSE and MAE are: (1) computed and reported in the same units as the model output of concern and are hence easy for readers to interpret; (2) work well for continuous long-term simulations; and (3) commonly used in model performance evaluation. **Disadvantages:** Error indices are measured in the same unit as the model output being investigated, so they cannot be used by themselves to gauge model performance for values other than zero. **Notes:** RMSE and MAE can be used to determine confidence intervals in model predictions, and it is possible to incorporate measurement uncertainty (Harmel and Smith, 2007; Harmel et al., 2010).
MAE	$\frac{1}{n}\sum_{i=1}^{n}\left\|O_i-P_i\right\|$	0.0 to ∞	0.0	
RSR	$\frac{\sqrt{\sum_{i=1}^{n}\left(O_i-P_i\right)^2}}{\sqrt{\sum_{i=1}^{n}\left(O_i-\bar{P}\right)^2}}$	0.0 to ∞	0.0	**Advantages:** RSR incorporates the benefits of error index statistics and includes a scaling/normalization factor, so the resulting statistics and reported values can apply to various output responses. **Disadvantages:** RSR gives more weight to high values when compared with low values because errors in high values are usually greater in absolute value than errors in low values due to the squared difference values in the denominator. **Notes:** RSR has not been widely used in the H/WQ modeling literature since it is a relatively new statistical performance measure.

Table 5 (continued). Equations, ranges, optimal values, and advantages and disadvantages for statistical performance measures in the Moriasi et al. (2012) special collection (O and P are observed and predicted values, respectively).

Statistic	Equation	Range	Optimal Value	Advantages/Disadvantages
RE or PE	$\left\lvert\frac{O_i - P_i}{O_i}\right\rvert \times 100$	0.0 ∞ to ∞	0.0	**Advantages:** (1) RE facilitates comparison of model performance between different output responses, and (2) differences between observed and predicted values are quantified as relative deviations. This significantly reduces the influence of absolute differences during high flows. **Disadvantages:** The absolute lower differences during low flow periods are enhanced because they are significant if looked at in a relative sense. As a result, there might be a systematic over- or underprediction during low flow periods. **Notes:** RE can be used along with other statistics to quantify low flow simulations
PBIAS	$\frac{\sum_{i=1}^{n} O_i - P_i}{\sum_{i=1}^{n} O_i} \times 100$	-∞ to ∞	0.0	**Advantages:** PBIAS: (1) can be used to determine how well the model simulates the average magnitudes for the output response of interest; (2) is useful for continuous long-term simulations; (3) is robust and commonly used, which means that there is extensive information on reported values; (4) can help identify average model simulation bias (overprediction vs. underprediction); and (5) can incorporate measurement uncertainty (Harmel et al., 2010). **Disadvantages:** PBIAS cannot be used (1) for single-event simulations to identify differences in timing and magnitude of peak flows and the shape of recession curves nor (2) to determine how well the model simulates residual variations and/or trends for the output response of interest. **Notes:** PBIAS can give a deceiving rating of model performance if the model overpredicts as much as it underpredicts, in which case PBIAS will be close to zero even though the model simulation is poor. It is therefore recommended that PBIAS be used with other statistical and graphical PMs to determine model performance.

The mean absolute error (MAE) is also measured in the same units as the model output response of interest. It is usually similar in magnitude but slightly smaller than the RMSE. The RMSE also tends to give more weight to high values than low values because errors in high values are usually greater in absolute value than errors in low values (Gan et al., 1997; Gan and Biftu, 1996; Eckhardt and Arnold, 2001; van Griensven and Bauwens, 2003; Huisman et al., 2003; Cho and Olivera, 2009). To get around this limitation, Moriasi et al. (2007) recommended that RMSE be normalized using the observations standard deviation, giving a measure referred to as the RMSE-observations standard deviation ratio (RSR).

Although it is commonly accepted that the lower the RMSE, the better the model performance, only Singh et al. (2004) published a guideline to qualify what is considered a low RMSE based on the observations standard deviation (SD). Singh et al. (2004) stated that RMSE values of less than half of the SD of the observations may be considered low. Based on the recommendation by Singh et al. (2004), Moriasi et al. (2007) developed the RSR.

Relative error (RE), absolute relative error, or absolute relative deviation is the ratio of absolute error of the simulated data to the observed data. It indicates the mismatch that occurs between the observed and modeled values, expressed in terms of ratios and percentages. Krause et al. (2005) recommended relative efficiency criteria for NSE and *d* in which relative deviations are derived for NSE and *d*. These can be used to quantify low flow simulations. Relative bias (RB), relative volume error (RVE), and many other bias-based statistics are derived based on RE to report statistical PMs in evaluating hydrological model performances.

Percent bias (PBIAS) measures the average tendency of the simulated data to be larger or smaller than observed counterparts (Gupta et al., 1999). It also measures over- and underestimation of bias and expresses it as a percentage. Percent stream flow volume error (PVE; Singh et al., 2004), prediction error (PE; Fernandez et al., 2005), and percent deviation of stream flow volume (D_v; ASCE, 1993; Moriasi et al., 2007) are calculated in a similar manner as PBIAS.

Meta-Analysis of Performance Data

Reported Value Ranges for Performance Measures

For each model included in the Moriasi et al. (2012) special collection, approximately 20 available peer-reviewed articles were collected. Performance data for case studies in the Moriasi et al. (2012) special collection and for articles reviewed by Moriasi et al. (2007) were not considered in this study. While this effort was by no means exhaustive, it yielded a sizeable dataset including 312 data points for R^2 and 435 data points for NSE that were used in the meta-analysis. Due to the volume of material involved, reported performance data for each simulated component during calibration and validation were recorded (supplemental material tables S1-1 through S1-22, available at http://bit.ly/NRES_SW10715). These data were collected from articles published from 1992 to 2013; 93% were published in 2000 or later, and 53% were published after 2007. Most of the reported parameters are for field-scale (tables S1-2 to S1-10) and watershed-scale (tables S1-11 to S1-22) models that utilize both manual and autocalibration methods. Of the reviewed articles, most reported model calibration and validation on flow-related components (tables S1-2 to S1-5 and S1-11 to S1-15), and most are based on the

SWAT model. The least reported model calibration and validation PM values were those associated with point to plot scale models (table S1-1). Most of the models in this category utilize autocalibration algorithms that select all possible combinations of solutions that meet the set threshold for the selected objective function.

Of the models examined (table 1), only SWAT, HSPF, WARMF (watershed-scale), and ADAPT (field-scale) had sufficient model performance data for meaningful analyses. The total numbers of reviewed articles from which data were obtained for analyses of SWAT, HSPF, WARMF, and ADAPT models were 33, 17, 2, and 16, respectively. For each of the aforementioned models, values for R^2, NSE, and PBIAS were reported most frequently, but there was also an appreciable amount of data on the index of agreement (*d*) at field scale. Based on reviewed literature, point to plot (and to some extent field-scale) models used different simulated response outputs to evaluate model performance. For instance, Essaid et al. (2008) and Healy and Essaid (2012) used streambed water flux and temperature to evaluate VS2DI performance, while Huth et al. (2012) used soil water content to evaluate SWIM3. Krobel et al. (2010) and Diekkruger et al. (1995) also used soil water content to evaluate the performance of the DAISY model. The use of different simulated response outputs and the limited amount of reported peer-reviewed model performance data made it difficult to conduct statistical comparisons for these smaller spatial scale models, so they were excluded from the analysis and PEC development.

Table 6. Summary of the performance data used for detailed statistical analyses.

[a] Blank entries mean that either there were no data or that available data were insufficient for meaningful statistical analyses. All available raw data are presented in the supplemental material tables (available at http://bit.ly/NRES_SW10715).

Preliminary Diagnostics of Data Used for Meta-Analysis

Table 6 summarizes the data used for the meta-analysis. Based on a preliminary analysis, reported performance data values for watershed-scale models, irrespective of output response and temporal scale, varied from 0.02 to 1.00 for R^2, from -10.30 to 0.99 for NSE, and from -81.1% to 167% for PBIAS (table 4). Reported R^2 values for field-scale models for flow at a monthly temporal scale varied from 0.18 to 0.91, while *d* values varied from 0.60 to 0.99 (table 6).

Further analysis of the distributions of the combined datasets (regardless of whether they pertained to calibration or validation, watershed size, and/or the components) showed that most tended to be skewed toward the higher values of the specific PMs (table 6 and fig. 2). This was expected because calibration and validation efforts are usually geared toward finding the best suitable values, which are the highest values for measures such as R^2, NSE, and *d*. Exceptions to this trend were values of PBIAS, which were more centrally located. Again, this is not surprising, as

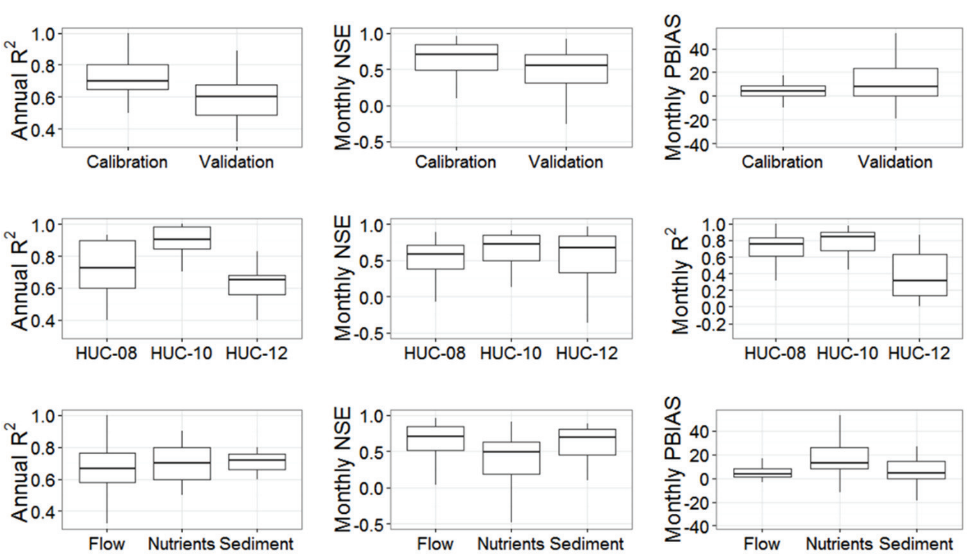

Figure 2. Box and whisker plots showing comparisons of performance data considering: (top row) calibration and validation, (middle row) watershed size (HUC-08 includes data for watersheds at HUC 8 and larger), and (bottom row) simulated component.

PBIAS can vary between small and large values, both negative and positive, and by definition PBIAS values close to zero indicate better model performance and are thus more desirable. The other exception was R^2 values, for which the data were approximately normally distributed. At this point, it is unclear why this was the case. Based on the approximate distributions of the performance data, the non-parametric median test was used to test whether there were significant differences among reported performance values data (table 7) among the various categories to warrant development of separate PEC.

For most of the watershed-scale analyses performance data, values for calibration were significantly different (table 7) from those reported for validation, with those for calibration being better (fig. 2). This was not the case for the field-scale data, for which the performance data values were not significantly different between the calibration and validation periods. Ideally, performance values obtained for validation need to be close to those obtained during calibration; a discrepancy between these values is evidence of model divergence (Sorooshian and Gupta, 1995; Duda et al., 2012; Zheng et al., 2012), suggesting calibrated model inaccuracies in process representation (Sorooshian, 1983). Since calibration efforts rely on comparisons between observed and measured data, it is possible to make parameter adjustments simply to suit this kind of comparison while ignoring the accuracy of the process simulation. Thus, in recommending guidelines, we do not make a distinction between calibration and validation periods.

Significant differences were also observed in reported performance data values at the watershed scale, with the exception of monthly NSE values (table 7 and fig. 2). Although no clear patterns were discernible, the models seemed to perform better for HUC-10 watersheds than for HUC-08+ and HUC-12 watersheds. Similarly, at each temporal scale, there were significant differences among PMs based on the response output being simulated and the available data for reported model PM values (table 7). For example, data analysis indicated better simulation of flow than all other response outputs. This was expected, given that hydrologic processes are the primary drivers within a watershed; thus, associated simulated response outputs are calibrated first and more extensively. In addition, more observed data are available to calibrate models for flow than for sediments or nutrients.

Further analyses based on both simulated response output and temporal scale (e.g., annual flow, monthly flow, etc.) also showed significant differences for R^2 and NSE ($p = 0.0002$ and 0.0001, respectively), although no significant differences were observed among the temporal scales when all data were grouped together and analyzed solely by temporal scale ($p = 0.0661$, 0.1957, and 0.0811 for R^2, NSE, and PBIAS, respectively). Due to the difficulties in duplicating the timing of flow, and given the uncertainties in the timing of model inputs (mainly precipitation; Duda et al., 2012), model calibration is considered to be simpler at the annual temporal scale and is progressively more difficult as the temporal scale resolutions becomes finer (Engel et al., 2007; Moriasi et al., 2007; Duda et al., 2012). Thus, this latter finding was somewhat surprising. However, the art of model calibration has greatly improved in recent years due to model autocalibration tools and techniques. These are designed to find optimal parameters based on PMs, hence increasing the likelihood that resulting model PM values will be comparable regardless of the temporal scale.

Based on the meta-analysis results, we determined that there was a need for separate PEC for each of the commonly simulated response outputs, watershed- and field-scale models, temporal scales, and for the recommended PMs.

Table 7. Summary of results of the statistical analyses on the performance data.

[a] Probability that observed differences in reported performance data values are attributable to error or chance given an α level of significance ($\alpha = 0.05$ in this case). Values <α indicate that the reported performance data values (e.g., for calibration vs. validation) are significantly different at that level of significance, with smaller values indicating higher significance (i.e., probability that observed differences were due to error or chance is very small). Asterisks (*) indicate significant differences in performance data values for calibration vs. validation, HUC, and modeled component.

[b] Combines data for stream flow, surface runoff, and base flow as reported.

However, there was also the need for general PEC that could be used across temporal scales. The final recommended PEC for the identified separate categories are based primarily on the results of computed percentiles of reported performance data to determine thresholds for the different qualitative ratings used in this article, existing PEC (Al-Qurashi et al., 2008; Moriasi et al., 2007; Duda et al., 2012; Herr and Chen, 2012; Ma et al., 2012; Skaggs et al., 2012; Wang et al., 2012), and our modeling experience.

Development of Criteria for Selected Statistical Performance Measures

The final step of the meta-analysis was to compute percentiles of available performance data to develop separate PEC for R^2, NSE, PBIAS, and *d* for the spatial and temporal scales and simulated response outputs identified by the median test in the previous subsection. There were 57 negative NSE values reported for watershed-scale models (supplemental material tables S1-11 to S1-20). However, by definition, NSE < 0.0 indicates that the mean observed value is a better predictor than the simulated value, which indicates unacceptable performance. Therefore, all negative values for NSE were excluded. While we agree that NSE is more stringent than R^2 or *d*, we did not exclude any reported performance data for R^2 and *d* corresponding to the studies that reported negative NSE. This is because different PMs have varied strengths that aid in determining the performance of a given model during the calibration and validation periods. Therefore, the reported performance data for each PM were analyzed independently.

To be consistent with model PEC previously recommended by Moriasi et al. (2007), "very good," "good," "satisfactory," and "not satisfactory" ratings were defined. Initial PEC were then developed for each of the ratings based on different data distributions at spatial and temporal scales and simulated response outputs for the recommended criteria. Even though percentile is used to measure spread, we also found it appropriate to use as an initial step in determining the thresholds for the defined ratings due to the fact that the calibration process seeks to optimize PMs for response outputs of interest. Considering the ranges of model PM data obtained (table 6) and expected reasonable PM data values, model performance values at and below the 25th percentile were considered "not satisfactory," model performance values between the 25th to 50th percentiles were considered "satisfactory," model performance values within and including the 50th to 75th percentiles were considered "good," and those above the 75th percentile were considered "very good." Values obtained based on percentiles were adjusted accordingly (e.g., rounded off) to produce meaningful intervals for these initial PEC. Figure 3 shows an example of the PEC development process. To facilitate PEC development for PBIAS, all related entries were converted into absolute values (fig. 3b). Because of the nature of this statistic, the rating and corresponding percentile ranges were reversed.

Analysis of the initial PEC based on data distributions resulted in several noteworthy differences (table 8). For example, with NSE, the resulting PEC for flow were different from those for N and P, with the former PEC being stricter. This was expected due to the large amount of observed flow calibration data, which is not the case for sediment and nutrient data. It is also critical that flow simulation be accurate, as flow is the primary driver of watershed processes. Sediment seemed to exhibit a similar response to flow, possibly for the same reasons. This explains why PEC were stricter for flow than for N and P.

[a] Values are absolute.

With regard to temporal scale, however, the distinctions were not as clear. While data were not always sufficient to allow comparisons for each component, in some instances the resulting PEC were contradictory, e.g., initial PEC were stricter for monthly flow than for annual flow. This was in contrast to Moriasi et al. (2007), who suggested more relaxed PEC for a daily temporal scale and progressively higher thresholds for subsequent coarser temporal scales. As previously discussed, our data did not show significant differences on the basis of temporal scale alone, which could possibly explain these discrepancies. For each of the PMs, general initial PEC (table 8) were also derived independent of either component or temporal scale and seemed to offer more unifying values that could be used as alternates where contradictions were encountered.

As a final step, the initial PEC were reviewed and revised based on previous PEC as reported in the literature (Al-Qurashi et al., 2008; Moriasi et al., 2007; Duda et al., 2012; Herr and Chen, 2012; Ma et al., 2012; Skaggs et al., 2012; Wang et al., 2012) and on our modeling experience. The final PEC developed are reported under the "Guidelines for Model Performance Evaluation: Recommended Measures and Criteria" subheading.

Guidelines for Model Performance Evaluation: Recommended Measures and Criteria

Prior to providing any general recommendations for model PMs and their corresponding PEC, we note that it is critical that model users follow proper calibration and validation procedures to obtain the correct model performance for the right reasons (Kirchner, 2006; Arnold et al., 2015). In this regard, we recommend that model users should consider recommendations for all other key calibration and validation topics covered in this special collection. These include (1) ensuring that terminology is clearly defined (Zeckoski et al., 2015), (2) selecting an appropriate model based on the study goals and ensuring that the model and fluxes are well represented (Arnold et al., 2015), (3) considering appropriate spatial and temporal scales (Baffaut et al., 2015), (4) parameterizing the model appropriately

(Malone et al., 2015), and (5) employing appropriate calibration and validation strategies (Daggupati et al., 2015b), including sensitivity (Yuan et al., 2015) and uncertainty (Guzman et al., 2015) analyses. Having taken all these important modeling aspects into consideration, model users should then use appropriate PMs along with the corresponding general PEC recommended in this article. Finally, we recommend that all these aspects of modeling be properly documented and reported (Saraswat et al., 2015) with sufficient detail to ensure repeatability.

The first step in evaluating model performance is to use recommended graphical PMs because they provide a visual indication of model performance. The next step is to compute values for the recommended statistical PMs. The computed values are then compared with recommended PEC to assess model performance with respect to statistical PMs.

Recommended Performance Measures

Due to varied strengths of the different PMs described in this article, we recommend the use of multiple graphical and statistical PMs. Both direct and derived graphical PMs are recommended in determining model calibration and validation performance. For shorter periods and coarse temporal resolutions (e.g., monthly calibration for one to three years), time series and scatter plots are most effective for data visualization and demonstration of model performance. With increasing data points, an inconsistent understanding of model performance may result from direct graphical PMs. Under such circumstances, derived measures such as cumulative distributions or duration curves should be employed. For field- and watershed-scale models, where calibration and validation are done at the outlet, we recommend using maps to ensure that non-calibrated locations provide reasonable values for outputs of interest such as soil erosion or nutrient loss. This will ensure a more comprehensive evaluation of model performance and confidence in model outputs.

The most commonly used statistical PMs with varied complementary strengths are recommended. These include R^2 (in conjunction with the gradient b and the intercept a of the corresponding regression line), NSE, d, RMSE alongside RSR, and PBIAS. These statistics can be used for daily, monthly, and yearly temporal scales and for all major output responses. During low flow simulations, logarithmic or relative derivatives of NSE or d need to be used, as recommended by Krause et al. (2005). We also recommend that RSR be reported alongside RMSE, with RMSE providing model performance in the units of the output response of interest and RSR providing a normalized value for comparison of model performance for various studies.

Recommended Performance Criteria

The recommended PEC for the statistical PMs NSE, R^2, d, and PBIAS for different output responses at different spatial and temporal scales are presented in table 9. The PEC in table 9 result from a combination of previous PEC as reported in the literature (Al-Qurashi et al., 2008; Moriasi et al., 2007; Duda et al., 2012; Herr and Chen, 2012; Ma et al., 2012; Skaggs et al., 2012; Wang et al., 2012), meta-analysis conducted in this study, and our modeling experience. For a given study, the same PBIAS PEC are recommended for the three temporal scales because PBIAS is computed based on observed daily, monthly, and annual values derived from data collected or measured at a finer temporal scale, such as hourly or sub-hourly. These PEC apply to both model calibration and validation periods. For example, based on table 9, model performance can be judged as “satisfactory” for flow simulations if monthly $R^2 > 0.70$ and $d > 0.75$ for field-scale models and daily, monthly, or annual $R^2 > 0.60$, NSE > 0.50, and PBIAS ≤ ±15% for watershed-scale models. Although we recommend RMSE (with RSR) and the logarithmic or relative derivative of d or NSE statistical PMs, no PEC were developed for them because the available data were not sufficient for meta-analysis and thus for PEC development. However, for RSR, we recommend that the PEC proposed by Moriasi et al. (2007) be used until new PEC can be developed. The intent of this study was to develop generalizable PEC for all models. However, sufficient data for meta-analysis were available only for SWAT, HSPF, WARMF, and ADAPT, as mentioned earlier. Therefore, we also recommend that the PEC developed in this study be used primarily for these models and used only with caution for other models. For example, in the absence of spatial-specific model criteria, the stated watershed PMs and corresponding criteria can be adopted and/or modified for oth-

Table 9. Final performance evaluation criteria for recommended statistical performance measures for watershed- and field-scale models.

[c] Where there were no differences, PEC were grouped for the output responses.

er spatial scale models.

The PEC recommended in this study are general and can be adjusted as appropriate. However, we consider some values of the recommended PMs to be unacceptable beyond certain reasonable ranges. For example, as explained earlier, we consider negative values of NSE to indicate unacceptable model performance. Unacceptable values of PBIAS can be derived from Harmel et al. (2006), with maximum measurement uncertainties under typical measurement scenarios considered to be ±19% for stream flow, ±69% for nitrate-N (NO_3-N), ±100% for ammonium-N (NH_4-N), ±70% for total N, ±104% for dissolved P, ±110% for total P, and ±53% for total suspended sediments (TSS). Al-Qurashi et al. (2008) defined acceptable performance for flow simulations as being within 30% of observed values for KINEROS/AGWA (Goodrich et al., 2012). For performance measure *d*, Krause et al. (2005) stated that high values of *d* (over 0.65) were reported even for poor model fits. In this article, the minimum *d* value obtained as reported in literature was 0.60, and the overall minimum R^2 value reported in literature and used in the meta-analysis in this article was 0.18. Such low values do not provide much information about model performance and, similar to NSE < 0.0, can indicate that the mean observed value is a better predictor than the simulated value.

Thus, in this article, $R^2 < 0.18$, NSE < 0.0, PBIAS ≥ ±30% for flow, PBIAS ≥ ±55% for sediments, PBIAS ≥ ±70% for nutrients, and $d < 0.60$ represent unacceptable model performance.

ADDITIONAL CONSIDERATIONS

The recommendations for model PMs and their corresponding PEC presented in the previous section apply to the typical case of continuous, long-term simulation for the given output responses at specified spatial and temporal scales (table 9). However, because of the diversity of modeling applications, these recommendations may be adjusted based on the quality and quantity of available measured data, spatial and temporal scales, and project scope and magnitude. It is also important to note that the recommended PMs are based only on the measures reported primarily in the Moriasi et al. (2012) special collection. Therefore, we have provided some additional considerations in this subsection to assist users in their calibration and validation efforts.

The PEC results presented herein are based on a meta-analysis of a selection of published data. As mentioned earlier, this body of data is not all-inclusive; this work can be extended by including data from a more extensive body of literature. However, in order to maintain the integrity of the database, article selection and data collection must be subject to the same considerations and follow the same procedures as outlined in this work. It is also important to note that substantial advances have been made in model calibration and validation such that it is now possible to obtain far better model performance and parameter representation than was possible at its nascence. Thus, we do not recommend the inclusion of historical and early development and application works, as resulting criteria may not be representative of the current state-of-the-art. We suggest using works only from the last 20 years.

A major limitation of the meta-analysis is the exclusion of unpublished data. In further extending the analysis, we recommend, inasmuch as is possible, identification and inclusion of unpublished material that fit all other criteria as outlined under key considerations in the "Meta-analysis of Performance Data" subsection. The use of only published material in this work has its strengths and weaknesses; while the results are based on data that has undergone a thorough quality assurance and quality review via the peer-review process, a weakness is that typically only good results (with the best performance data values) are published, likely contributing to the lack of distinction among temporal scales. This effect might not be discernible at other levels of analysis since the datasets at those levels are much smaller.

Finally, we recommend presenting summary statistics such as the mean, median, percentiles, and standard deviation of the observed and simulated response outputs. This information is useful and can provide benchmarks for follow up studies.

Residual Analysis

The residual (or error) is the difference between individual observed and simulated values; these values represent the uncertainty of the simulation. Ideally, the residuals should be close to zero and normally distributed. Any skew indicates a systematic bias, which could be potentially resolved by further calibration. Bennett et al. (2013) observed that residual analysis was an important part of model evaluation. They recommended using residual or QQ plots to examine any systematic divergence from zero. Residual plots are graphs of the residuals against time or space, which are useful in identifying any systematic bias. In a QQ plot, quantiles of the residuals are plotted against Gaussian quantiles. This is helpful in determining if the distribution of residuals is normal. Jain and Sudheer (2008) demonstrated that residual analysis, such as checking for homoscedasticity (unsystematic variance), could result in additional insight and improved model evaluations. In addition to graphical analysis, Bennett et al. (2013) recommended calculating the MSE or RMSE of the residuals for a quantitative evaluation.

Despite its documented advantages, residual analysis continues to be a rarely used and/or sparsely reported practice in the modeling literature. Guidelines are needed for simplifying and integrating residual analysis into H/WQ model performance evaluation.

Quality and Quantity of Measured Data

The quality of measured data should be considered in evaluating model calibration and validation performance whenever such information is available (Harmel et al., 2006). According to Harmel et al. (2006), measured data are obtained under best-case, typical, and worst-case data quality scenarios. The best-case scenario represents procedures used with a concentrated effort in quality assurance/quality control (QA/QC), unconstrained by financial and personnel resource limitations, and in ideal hydrologic conditions. The typical scenario represents procedures conducted with a moderate effort at QA/QC and under typical hydrologic conditions. The worst-case scenario represents data measurements conducted with minimal attention to QA/QC, with limited financial and personnel resources, and in difficult hydrologic conditions. Harmel and Smith (2007) provide modified NSE, *d*, RMSE, and MAE statistics that account for measurement uncertainty. The recommended model PEC presented herein are for data of typical scenario quality. PEC should be stricter when data of best-case scenario quality are available and more relaxed where uncertainty is high (Moriasi et al., 2007). In such cases, however, users should not over-calibrate their models to obtain values of statistical performance measures better than the uncertainty of the available measured data. Harmel et al. (2010) provide adjustments that can be made to statistical PMs based on uncertainty in measured and simulated data. Alternative measures, such as comparison of means and other graphical PMs such as percentiles and frequency distributions, may be more appropriate for measured datasets derived from either incomplete or low-frequency sampling (Moriasi et al., 2007).

Spatial and Temporal Scale of Study

The recommended PEC are intended for field- to watershed-scale modeling studies and mainly for one or more temporal scales (daily, monthly, and annual) depending on the statistical PMs used and the model output response. More strict PEC are recommended for point to plot scale studies in which there is less complexity of the processes involved and less uncertainty in model inputs (Guzman et al., 2015) due to the small spatial scale (Baffaut et al., 2015. For example, Ma et al. (2012) defined NSE > 0.70 and $R^2 > 0.80$ as acceptable model performance values for RZWQM2. It is also necessary to adjust the PEC as the temporal scale changes, utilizing stricter PEC as the evaluation temporal scale decreases from hourly to daily to annual (Moriasi et al., 2007).

Project Scope, Magnitude, and Intended Purpose

Moriasi et al. (2007) discussed the effects of scope and magnitude of the modeling project on model PEC, which should be taken into account when assessing model performance. More stringent PEC are recommended for projects that involve potentially large consequences, while the PEC may be relaxed for proof-of-concept studies. Similarly, Harmel et al. (2014) provided criteria for interpreting model results considering general intended use categories, which include exploratory, planning, and regulatory/legal.

Calibration vs. Validation Performance Criteria

Although prior studies have recommended different PEC for calibration and validation periods (e.g., Moriasi et al., 2007), and our analyses showed significant differences in reported values, this should not be the case. Based on discussions in Sorooshian and Gupta (1995) and Sorooshian (1983), this occurrence in some cases points to inaccuracies in process representation. In other cases, differences in performance during the calibration and validation periods may indicate substantially different climate (Van Liew and Garbrecht, 2003) and land use data (Pai and Saraswat, 2011) and/or the need for further calibration. Thus, the recommended model PEC in this article apply for both the calibration and validation periods. It is also essential to use observed calibration and validation data at spatial and temporal scales that are consistent with the model computations; otherwise, a justification should be provided (Baffaut et al., 2015; Daggupati et al., 2015b).

Framework for Updating Recommended Model Performance Measures and Evaluation Criteria

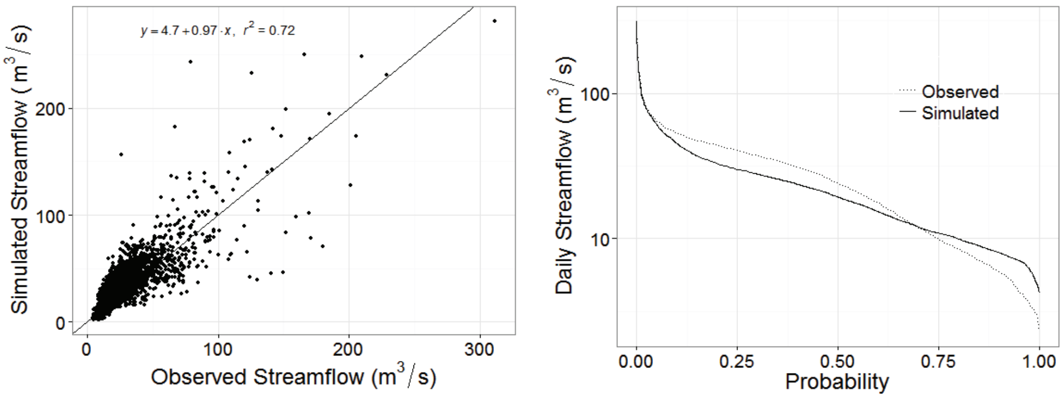
This initial meta-analysis sets the stage for a more comprehensive meta-analysis including a broader range of articles (including unpublished material) and covering a larger suite of models. To assist with this future endeavor, we present a framework for determining recommended model PMs and their corresponding PEC. The framework consists of (1) reviewing current modeling literature to determine the PMs used and collect study-specific calibration and validation data as reported and (2) developing PEC for the recommended PMs based on a meta-analysis of a comprehensive dataset collected from published and unpublished sources while taking into account all key considerations described herein. The scope and limitations of the recommended PEC in this article have been clearly defined in prior sections but can be updated as more information becomes available. For future work, we recommend using performance data values reported for other models, for different output responses, and at various spatial and temporal scales both from published and unpublished literature. In addition, reported study-specific graphical PMs need to be recorded and discussed in depth.

We have established a database with an inventory of reported model performance values and respective study details (e.g., spatial scales, outputs, objective functions) to enable modelers to query and develop custom model PEC better suited to their study goals. This database can be extended frequently as H/WQ model PMs and related PEC continue to evolve and when new understandings of modeling science arise. We intend to make this database available in an open and user-friendly format to provide opportunities for updates through crowd-sourcing. The analysis framework and the developed database will enable modifications of the recommended PMs and PEC as more information is obtained.

Demonstration of Recommended Model Performance Measures and Criteria

An example case study was conducted with a hypothetical watershed-scale H/WQ model. The model was calibrated at the outlet for stream flow on a daily temporal scale for ten years (2001 to 2010). The model name and the study location are not mentioned here to emphasize the generic nature of the guidelines. Figure 4 and table 10 show the graphical and statistical performance of the model based on the recommended PMs.

Since this is a daily temporal scale, ten-year evaluation, the recommended graphical PMs are the scatter plot and flow duration curves (fig. 4). Note that a time series graph was not recommended in this case because of the large dataset. The slope and intercept values are provided on the



(a) **(b)**

Figure 4. Graphical performance measures of a hypothetical model: (a) scatter plot and (b) flow duration curve.

Table 10. Statistical performance evaluation criteria of a hypothetical model.

Average		Standard Deviation		Statistics				
Measured	Simulated	Measured	Simulated	R^2	PBIAS (%)	NSE	RSR	RMSE
24.4	28.3	21.0	23.9	0.72 (slope 0.97, intercept 4.7) (Satisfactory)	-16 (Not satisfactory)	0.60 (Satisfactory)	0.63 (Satisfactory; Moriasi et al., 2007)	13.26

scatter plot based on the least square regression line. The slope of the line is close to a value of one, while the intercept is close to a value of zero, indicating good model performance. The flow duration curve shows that model predictions were close to the observed data for all flow regimes, although the model tended to underestimate the observed data during low flows (>80% probability), slightly overestimate during medium flows (>20% and <50% probability), and had a good agreement during high flows (>10%). By using this figure, a modeler and end user can easily visualize model performance and further identify parameters that can be tweaked to improve performance. For instance, in this case, parameters related to base flow can be adjusted, allowing the model to simulate slightly higher low flows.

Based on the statistical PMs, we can say that the model adequately captured the mean and standard deviation of the daily flow rates. Using the performance values in table 9, we can say that model performance was "satisfactory" based on R^2 and NSE, "not satisfactory" based on the PBIAS of -16%, and satisfactory based on the RSR of 0.63 (Moriasi et al., 2007). Adjustments can be made to model parameters to obtain better agreement among the PMs.

Although H/WQ models provide outputs in various file formats, performance evaluation is typically performed using a spreadsheet. However, setting up a spreadsheet to calculate the numerous graphical and statistical PMs can be a tedious task and prone to errors. Therefore, to support the task of model performance evaluation, a Microsoft Excel spreadsheet was developed (available at http://bit.ly/NRES_SW10715). The objectives of the spreadsheet are to (1) demonstrate the various statistical and graphical PMs discussed in the case study and (2) provide a starting point for H/WQ model users to conduct model performance evaluation.

In situations with conflicting performance ratings, we recommend that those differences be clearly described. For example, if simulation for one output variable in one watershed produces unbalanced performance ratings of "satisfactory" for R^2 and "unsatisfactory" for *d* for field-scale flow simulation, then the overall performance should be described conservatively as "unsatisfactory" for that one study area and that one model response output. However, we recommend that users describe model performance with respect to the degree of collinearity between simulated and measured data (R^2) as "satisfactory" and with respect to prediction error (*d*) as "unsatisfactory." Similarly, if performance ratings differ for various field- and watershed-scale studies and/or response outputs, then those differences need to be clearly described.

Summary and Conclusions

This is one of nine topic-specific articles in a special collection whose main goal is to provide recommendations that, together with recommendations by Harmel et al. (2014), will contribute toward the development of ASABE engineering practices for calibration and validation of H/WQ models. In this research, articles in the Moriasi et al. (2012) special collection were synthesized with respect to performance measures (PMs) and performance evaluation criteria (PEC). In addition, a detailed literature review centered on graphical and statistical PMs used by models described in the special collection was carried out to determine PMs to recommend for use. Further, an initial meta-analysis of performance data reported in literature (outside of the special collection) was performed to establish PEC for various PMs. Data were collected from articles published from 1992 to 2013; 93% were published in and after 2000, and 53% were published after 2007. Finally, specific guidelines for model performance evaluation were established based on the synthesis and results of the meta-analysis. Additional considerations were also presented to allow users to adjust recommended PMs and/or associated PEC to their specific needs. A framework for determining recommended model PMs and their corresponding PEC, based on a more comprehensive meta-analysis, was presented.

Based on the synthesis, we recommend that a combination of multiple graphical and statistical PMs be used for evaluating model performance. Recommended graphical PMs include time series, scatter plots, cumulative distribution, flow and load duration, and maps, while the recommended statistical PMs include R^2 (in conjunction with slope and intercept of the pertinent regression line), NSE, *d*, RMSE (together with RSR), and PBIAS.

In this study, we do not go further into specifying PEC based on watershed size, although further work would be needed in this regard. However, the results strongly suggest the need to provide PEC at different scales; therefore, we provide separate PEC for the watershed scale and the field scale. We do not provide (or even recommend) separate PEC for calibration and validation periods. Based on the meta-analysis results, previous PEC reported in the literature, and our modeling experience, recommended PEC are presented in table 9. In general, model performance can be judged "satisfactory" for flow simulations if monthly $R^2 > 0.70$ and $d > 0.75$ for field-scale models and daily, monthly, or annual $R^2 > 0.60$, NSE > 0.50, and PBIAS ≤ ±15% for watershed-scale models. Additionally, model performance can be judged "satisfactory" if monthly $R^2 > 0.40$ and NSE > 0.45 and daily, monthly, or annual PBIAS ≤ ±20% for sediment; monthly $R^2 > 0.40$ and NSE > 0.35 and daily, monthly, or annual PBIAS ≤ ±30% for P; and monthly $R^2 > 0.30$ and NSE > 0.35 and daily, monthly, or annual PBIAS ≤ ±30% for N. For RSR, we recommend that the PEC proposed by Moriasi et al. (2007) be used until new PEC are developed. These PEC, which apply to calibration and validation periods, may be adjusted to be more or less strict based on considerations of the quality and quantity of available measured data, spatial and temporal scales, and project scope, magnitude, and intended purpose. As more data become available and as new PMs are developed and used more frequently, the recommended PMs and their corresponding general PEC can be adjusted based on the framework developed in this study.

However, we consider some values of the recommended statistical PMs to be unacceptable beyond certain reasonable ranges. Thus, in this article, $R^2 < 0.18$, NSE < 0.0, PBIAS ≥ ±30% for flow, PBIAS ≥ ±55% for sediment, PBIAS ≥ ±70% for nutrients, and $d < 0.60$ represent unacceptable model performance. An example case study and an Excel spreadsheet are provided to illustrate the application of the recommended PMs and the corresponding developed PEC guidelines.

The guidelines developed in this study go beyond the scope of those provided by Moriasi et al. (2007), which were limited to NSE, PBIAS (Gupta et al., 1999), and RSR for stream flow, sediment, and nutrient (N and P) simulations at a monthly temporal scale and watershed spatial scale. In this study, PEC for R^2 were added and PEC for NSE were disaggregated by output parameter (flow, sediment, N/P), and limits were adjusted based on current data. Limits were also adjusted for PBIAS for each output parameter, and some PEC were explicitly extended to daily and annual scales. In addition, PEC for R^2 and *d* were added for ADAPT. These current results provide updated guidance on performance measures and corresponding performance evaluation criteria for calibrating and validating hydrologic and water quality models.

ACKNOWLEDGEMENTS

The authors are grateful to Dr. Dharmendra Saraswat, Dr. Colleen Rossi, Dr. Sanjay Shukla, and Dr. Prasanna Gowda for their initial support of these efforts. We also thank all those who reviewed the manuscript.

APPENDIX

ABBREVIATIONS FOR MODEL NAMES

ADAPT	Agricultural Drainage and Pesticide Transport
AGWA	ArcGIS-based Automated Geospatial Watershed Assessment
APEX	Agricultural Policy/Environmental eX-tender
BASINS	Better Assessment Science Integrating Point and Nonpoint Sources
COUPMODEL	Coupled Heat and Mass Transfer model
CREAMS	Chemicals, Runoff, and Erosion from Agricultural Management Systems
DAISY	Danish Simulation Model
EPIC	Erosion Productivity Impact Calculator
GLEAMS	Groundwater Loading Effects of Agricul-tural Management Systems
HSPF	Hydrological Simulation Program - Fortran
H/WQ	Hydrologic and water quality (models)
HYDRUS	-
KINEROS	KINematic runoff and EROSion
MIKE SHE	MIKE System Hydrologique European (SHE)
MT3DMS	Modular 3-Dimensional Multispecies Transport Model
RZWQM	Root Zone Water Quality Model
SHAW	Simultaneous Heat and Water
STANMOD	STudio of ANalytical MODels
SWAT	Soil and Water Assessment Tool
SWIM	Soil Water Infiltration and Movement
TOUGH	Transport of Unsaturated Groundwater and Heat
VS2DI	-
WAM	Watershed Assessment Model
WARMF	Watershed Analysis Risk Management Framework
WEPP	Water Erosion Prediction Project

STATISTICAL TERMS AND PERFORMANCE MEASURES

d	Index of agreement
D_v	Deviation volume
HUC	Hydrologic unit code
MAE	Mean absolute error
ME	Mean error
MSE	Mean square error
NSE	Nash-Sutcliffe efficiency
PBIAS	Percent bias
PE	Prediction error
PPS	Point to plot scale
PVE	Percent volume error
r	Pearson's correlation coefficient
R^2	Coefficient of determination
RB	Relative bias
RE	Relative error
RMSD	Root mean square deviation
RMSE	Root mean square error
RSR	RMSE-observations standard deviation ratio
RVE	Relative volume error
SD	Standard deviation

Appendix 30A

Specifications for Runs 15 – 18

and

Specifications for Simulated WWTP Discharges and Urban Deep Percolation

ILRG Model

Early EPCWID Ops (WWTP & Fabens Drains) (Run 15)
Early EPCWID Ops (WWTP) (Run 15a)
Early EPCWID Ops (Fabens Drains) (Run 15b)
Early EPCWID Ops (TX Hueco Pumping Off) (Run 15c)

Irrigation Pumping

- Supplemental pumping to meet unmet demand after use of surface water.
  - **Run 15c**: Texas Hueco pumping off.
- Pumping on NM primary ground water acres to meet crop demand.

Non-Irrigation Pumping and Returns

- Historical non-irrigation pumping and returns.
  - **Run 15c**: Texas Hueco pumping off.

Irrigated Area

- Project Acres: Historical
- HCCRD and MX Acres: Historical
- NM Primary GW Acres: Historical

Crop Evapotranspiration

- Historical.

Irrigation Infrastructure and Irrigation Practices

- EBID: Historical
- HCCRD: Historical
- Mexico: Historical
- EPCWID
  - **Run 15 & 15c**:
    - Charge EPCWID for use of EPW WWTP returns.
    - No ACE or Haskell credits for EPCWID.
    - Simulate EPCWID (EPV) increased use of Fabens drain flows*.
    - Charge EPCWID for use of Fabens drain flows.
  - **Run 15a**:
    - Charge EPCWID for use of EPW WWTP returns.
    - No ACE or Haskell credits for EPCWID.
  - **Run 15b**:
    - Simulate EPCWID (EPV) increased use of Fabens drain flows*.
    - Charge EPCWID for use of Fabens drain flows.

* Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 af/month for irrigation in EPCWID.

Project Allocation Rules

- 1951-2005: D1/D2 Project allocation rules.
- 2006-2007: D3 Project allocation rules without carryover accounting.
- 2008-2017: D3 Project allocation rules with carryover accounting.

Conj Use 1: Hist All Acres D1/D2 (Hist M&I) (Run 16)

Conj Use 1a: Hist All Acres D1/D2 (1978 M&I) (Run 16a)

Irrigation Pumping

- Supplemental pumping to meet unmet demand after use of surface water.
- Pumping on NM primary ground water acres to meet crop demand.
- Limit 10-year average irrigation pumping to 1951-1978 averages:
  - NM: 166,866 AF (includes primary GW pumping)
  - TX: 81,971 AF (limit EPCWID+HCCRD)
    - EPCWID: 70,783 AF
    - HCCRD : 11,188 AF
  - MX: No limit

Non-Irrigation Pumping and Returns

- **Run 16 (Hist M&I):**
  - Historical non-irrigation pumping and returns.
  - Set Las Cruces returns from use of Jornada wells to zero (results in a simulated offset from return flows attributed to this imported water source).
- **Run 16a (1978 M&I):**
  - Limit annual M&I pumping to 1951-1978 maximums:
    - NM: 20,993 AF
    - TX (Hueco): 89,979 AF
    - TX (Mesilla): 30,264 AF
    - MX: No limit
  - Reduce M&I returns by same percentage as M&I pumping reduced:
    - For Las Cruces, this reduction applies to their use of Mesilla wells (not to their Jornada wells).
    - Don't reduce EPW returns from use of Project water.
  - Set Las Cruces returns from use of Jornada wells to zero (results in a simulated offset from return flows attributed to this imported water source).

Irrigated Area

- Project Acres: Historical
- HCCRD and MX Acres: Historical
- NM Primary GW Acres: Historical

Crop Evapotranspiration

- Historical.

Irrigation Infrastructure and Irrigation Practices

- EBID: Historical
- HCCRD: Historical
- Mexico: Historical
- EPCWID (Run 15 Conditions):
    - Charge EPCWID for use of EPW WWTP returns.
    - No ACE or Haskell credits for EPCWID.
    - Simulate EPCWID (EPV) increased use of Fabens drain flows*.
    - Charge EPCWID for use of Fabens drain flows.

* Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 af/month for irrigation in EPCWID.

Project Allocation Rules

- D1/D2 Project allocation rules from 1951-2017.

Conj Use 2: Hist Proj Acres (Hist M&I) (Run 17)
Conj Use 2a: Hist Proj Acres (Pre-Comp M&I) (Run 17a)

Irrigation Pumping

- Supplemental pumping to meet unmet demand after use of surface water (same as Historical Base Run).
- No pumping on NM primary ground water acres.

Non-Irrigation Pumping and Returns

- **Run 17 (Hist M&I)**:
  - Historical non-irrigation pumping and returns.
  - Set Las Cruces returns from use of Jornada wells to zero (results in a simulated offset from return flows attributed to this imported water source).
- **Run 17a (Pre-Comp M&I)**:
  - Limit M&I pumping to pre-Compact levels:
    - NM: 736 AF
    - TX: 13,744 AF
  - Reduce M&I returns by same percentage as M&I pumping reduced
    - For Las Cruces, this reduction applies to their use of Mesilla wells (not to their Jornada wells).
    - Don't reduce EPW returns from use of Project water.
  - Set Las Cruces returns from use of Jornada wells to zero (results in a simulated offset from return flows attributed to this imported water source).

Irrigated Area

- Project Acres: Historical
- HCCRD and Mexico Acres: Historical
- NM Primary GW Acres: None

Crop Evapotranspiration

- Historical

Irrigation Infrastructure and Irrigation Practices

- EBID: Historical
- HCCRD: Historical
- Mexico: Historical
- EPCWID (Run 15 Conditions):
  - Charge EPCWID for use of EPW WWTP returns.
  - No ACE or Haskell credits for EPCWID.
  - Simulate EPCWID (EPV) increased use of Fabens drain flows*.
  - Charge EPCWID for use of Fabens drain flows*.

* Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 af/month for irrigation in EPCWID.

Project Allocation Rules

- D1/D2 Project allocation rules from 1951-2017.

Conj Use 3: Auth Proj Acres (Pre-Comp M&I) (Run 18)

Irrigation Pumping

- Supplemental pumping to meet unmet demand after use of surface water (same as Historical Base Run).
- No pumping on primary ground water acres in EBID.

Non-Irrigation Pumping and Returns

- Limit M&I pumping to pre-Compact levels:
  - NM: 736 AF
  - TX: 13,744 AF
- Reduce M&I returns by same percentage as M&I pumping reduced
  - For Las Cruces, this reduction applies to their use of Mesilla wells (not to their Jornada wells).
- Set Las Cruces returns from use of Jornada wells to zero (results in a simulated offset from return flows attributed to this imported water source).
- No EPW use of Project water and no returns from EPW use of Project water.

Irrigated Area

- Project Acres: Set irrigated area to the original authorized Project acres in every year of the study period from 1940 – 2017:
  - EBID: 88,000 acres
  - EPCWID: 67,000 acres
- Other Acres: Set the irrigated area for HCCRD to the maximum historical acres which occurred in 1951, and use the actual historical acres that vary through time for Mexico:
  - HCCRD: 17,750 acres
  - MX: Historical acres (same as Base Run)
- NM Primary GW Acres: None

Crop Evapotranspiration

- Simulate the historical crop-weighted average unit crop irrigation requirement (CIR) for each irrigation district (EBID, EPCWID, HCCRD, Mexico); this reflects the historical changes in cropping pattern through time (same as Base Run).

Irrigation Infrastructure and Irrigation Practices

- Simulate the historical infrastructure as it evolved through time (same as Base Run).
- For all areas, simulate the historical water distribution losses, irrigation efficiency, deep percolation/surface runoff split, etc. as these changed through time (same as Base Run).
- EPCWID (Run 15 Conditions):
  - Charge EPCWID for use of EPW WWTP returns.
  - No ACE or Haskell credits for EPCWID.
  - Simulate EPCWID (EPV) increased use of Fabens drain flows*.
  - Charge EPCWID for use of Fabens drain flows*.

* Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 af/month for irrigation in EPCWID.

Project Allocation Rules

- D1/D2 Project allocation rules from 1951-2017.

Key to Simulated WWTP Discharges and Urban Deep Percolation for ILRG Model Runs

Description	WWTP Discharges ("WWTP")	Urban Deep Percolation ("UDP")
Base	All WWTP on.	All UDP on.
All Off	Turn off WWTP from NM Off, TX Off, and MX Off. Leave on WWTP from Haskell and Bustamante from EPW surface water diversions.	Turn off UDP from NM Off and TX Off.
NM Off	Turn off WWTP from Las Cruces, Salem, Hatch, Anthony NM, Gadsden School District, South Central Regional, Sunland Park and Santa Teresa, and El Paso Electric.	Turn off UDP from pumping from Las Cruces, Santa Teresa, Anthony NM, Mesquite, Berino, Garfield, and Radium Springs.
TX Off	Turn off WWTP from Anthony TX, Northwest, Socorro, and Fabens. Turn off WWTP from Haskell and Bustamante from EPW Mesilla and Hueco pumping. Leave on WWTP from Haskell and Bustamante from EPW surface water diversions.	Turn off UDP from Mesilla and Hueco pumping. Leave on UDP from EPW surface water diversions.
MX Off	Turn off WWTP from Juarez.	No MX UDP simulated in runs.
R-M Off	Turn off WWTP from NM Off and TX Mesilla Off. Turn off WWTP from Juarez Mesilla (Conjeos Medanos) pumping.	Turn off UDP from NM Off and TX Mesilla Off.
TX Mesilla Off	Turn off WWTP from Anthony TX and Northwest and WWTP from Haskell from EPW Mesilla pumping.	Turn off UDP from EPW Mesilla pumping. Computed as total EPW UDP multiplied by EPW Mesilla pumping divided by total EPW use.
All Hueco Off	Turn off WWTP from TX Hueco Off and MX Hueco Off.	Turn off UDP from TX Hueco Off.
TX Hueco Off	Turn off WWTP from include Socorro and Fabens. Turn off WWTP from of Haskell and Bustamante from EPW Hueco pumping. Leave on Haskell and Bustamante WWTP from EPW surface water diversions. Leave on Haskell WWTP from EPW Mesilla pumping.	Turn off UDP from EPW Hueco pumping. Computed as total EPW UDP multiplied by EPW Hueco pumping divided by total EPW use.
MX Hueco Off	Turn off WWTP from Juarez Hueco pumping. Leave on WWTP from Juarez Mesilla (Conejos Medanos) pumping.	All UDP on.
TX WWTP Off	Turn off WWTP from Anthony TX, Northwest, Haskell, Bustamante, Socorro, and Fabens.	All UDP on.
Base-Jornada	Turn off WWTP from Las Cruces from Jornada pumping. Computed as total Las Cruces WWTP multiplied by Jornada pumping divided by total Las Cruces pumping.	Turn off UDP from Las Cruces Jornada pumping. Computed as total Las Cruces UDP multiplied by Jornada pumping divided by total Las Cruces pumping .
1978 Max	For NM and TX, turn off WWTP from pumping that exceeds the maximum annual 1951-1978 pumping. Computed as WWTP multiplied by pumping reduction percentages.	For NM and TX, turn off UDP from pumping that exceeds the maximum annual 1951-1978 pumping. Computed as UDP multiplied by pumping reduction percentages.
PreComp GW	For NM and TX, set WWTP to pre-compact amounts. NM pre-compact WWTP is equal to the 1940 Hatch and Las Cruces amounts. TX pre-compact WWTP is equal to the 1938 Haskell amount. Leave on Haskell and Bustamante WWTP from EPW surface water diversions.	For NM and TX, set UDP to pre-compact amounts. NM pre-compact UDP is equal to the 1940 UDP from Hatch and Las Cruces pumping. TX pre-compact UDP is equal to the 1938 UDP from Haskell pumping. Leave on UDP from EPW surface water diversions.
PreComp	For NM and TX, set WWTP to pre-compact amounts. NM pre-compact WWTP is equal to the 1940 Hatch and Las Cruces amounts. TX pre-compact WWTP is equal to the 1938 Haskell amount.	For NM and TX, set UDP to pre-compact amounts. NM pre-compact UDP is equal to the 1940 UDP from Hatch and Las Cruces pumping. TX pre-compact UDP is equal to the 1938 UDP from Haskell pumping.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 2 - All Pumping Off

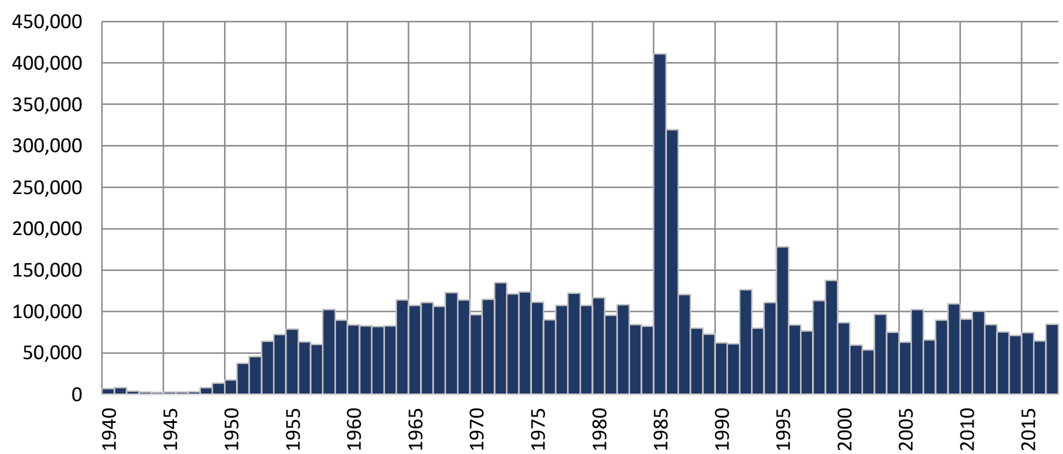
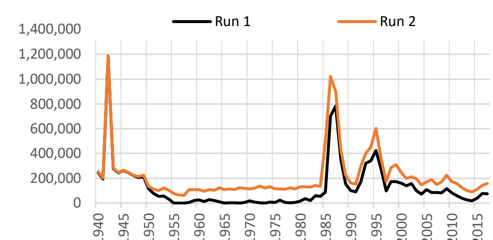
Rio Grande at Fort Quitman (Annual)



Period	Average Difference
1951-2017	100,304
1951-1978	94,449
1979-2005	113,419
2006-2017	84,456
1985-2017	105,499
1985-2005	117,524



Run 2 - All Pumping Off

Simulated Differences in ILRG Model Outputs

Run 2 minus Run 1

1940 - 2017 (acre-feet)

River Headgate (RHG) Diversions (Irrigation Season)

	Average Difference		
Period	EBID	EPCWID	HCCRD
1951-2017	50,298	21,264	12,980
1951-1978	52,206	23,239	14,465
1979-2005	4,579	17,121	11,910
2006-2017	148,716	25,977	11,922
1985-2017	57,978	21,373	11,873
1985-2005	6,128	18,741	11,845

Farm Headgate (FHG) Deliveries (Irrigation Season)

	Average Difference		
Period	EBID	EPCWID	HCCRD
1951-2017	34,570	12,259	2,649
1951-1978	33,891	18,830	6,406
1979-2005	9,451	4,142	-162
2006-2017	92,674	15,188	209
1985-2017	39,805	8,255	76
1985-2005	9,593	4,293	0

Notes:

(1) EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

(2) EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

(3) HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

(4) EPCWID FHG values include deliveries to Rogers WTP and R/U WTP.

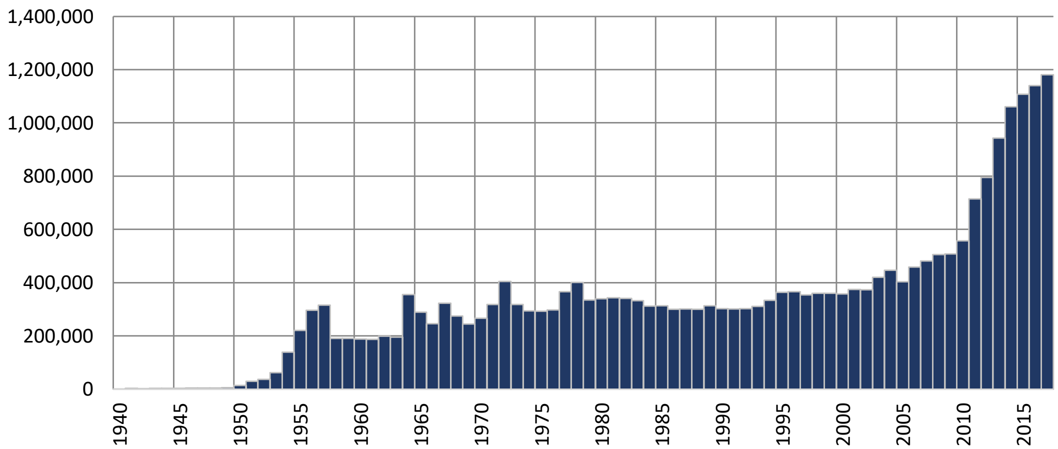
Run 2 - All Pumping Off

Simulated Differences in ILRG Model Outputs

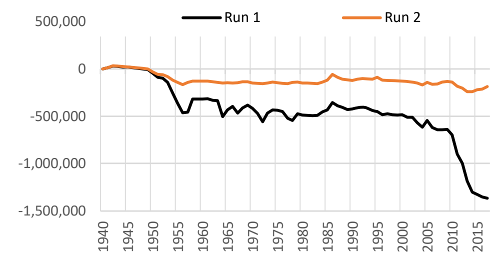
Run 2 minus Run 1

1940 - 2017 (acre-feet)

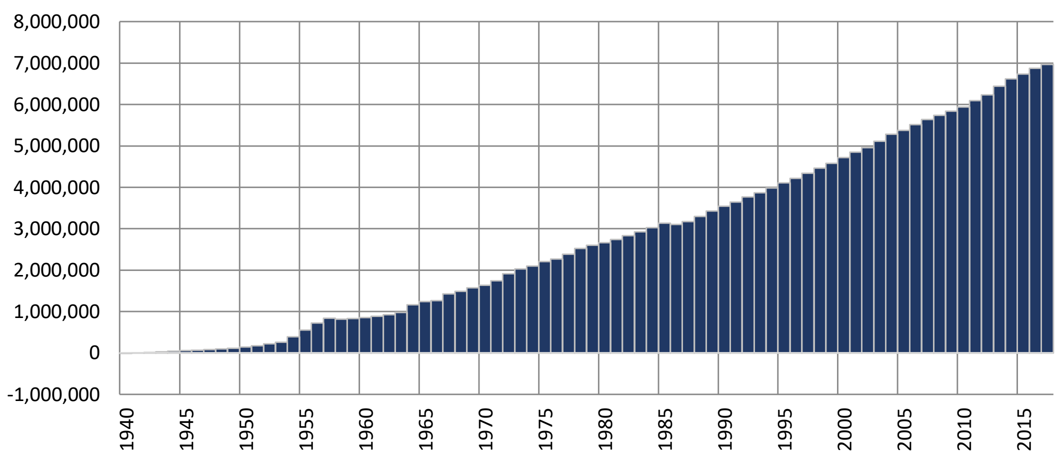
Cumulative Annual Rincon-Mesilla Groundwater Storage



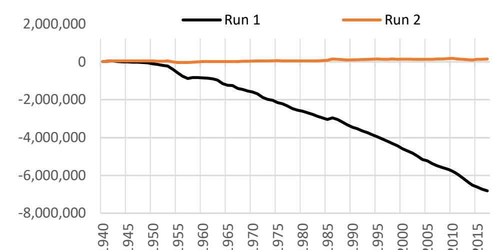
Period	Average Difference
1951-2017	17,417
1951-1978	13,807
1979-2005	96
2006-2017	64,812
1985-2017	26,339
1985-2005	4,354



Cumulative Annual Hueco Groundwater Storage



Period	Average Difference
1951-2017	101,839
1951-1978	84,954
1979-2005	105,574
2006-2017	132,836
1985-2017	119,492
1985-2005	111,867



Notes:

Cumulative storage change in alluvial and non-alluvial aquifers.

Average differences calculated as (Final Storage - Initial Storage)/(no. years).

Run 2 - All Pumping Off
Annual Allocation and Charges
Run 2 v. Run 1
ILRG Model
1950 - 2017 (acre-feet)

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

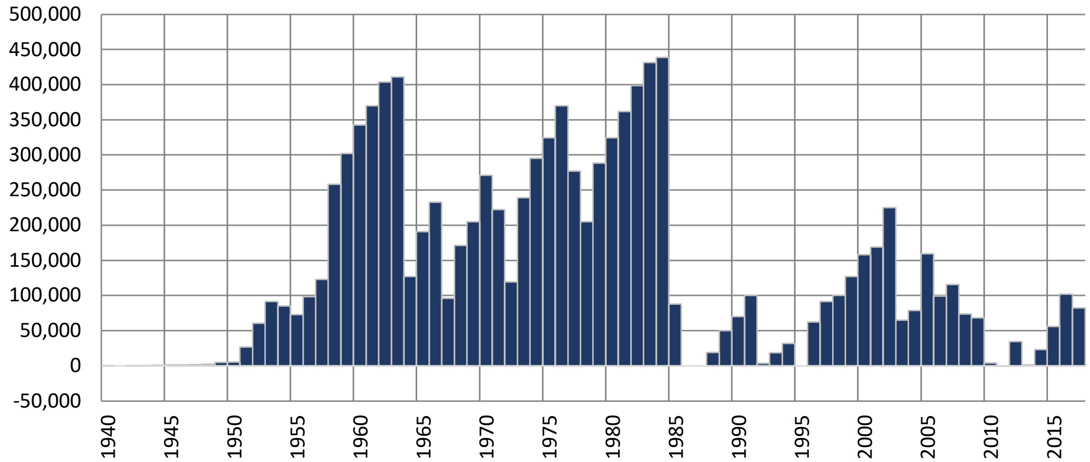
Run 3 - NM Pumping Off

Simulated Differences in ILRG Model Outputs

Run 3 minus Run 1

1940 - 2017 (acre-feet)

Total Project Storage (Year End)



Period	Average Difference

Model Run Specifications

Model Version: LRG_v116

Name: **Run 4 - TX Pumping Off**

Run ID: LRG_v116_Operational_Run4
Date: 8/28/2020

Name: **Run 1 - Historical Base Run**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

Pumping and Returns	Run 4	Run 1
Irrigation Pumping	TX Off	On
Irrigated Area	Hist	Hist
Non-Irrigation Pumping	TX Off	On
Non-Irrigation Pumping Returns	TX Off	On
Las Cruces Jornada Pumping Returns	On	On

Project Allocation Rules		
1950-2005	D1/D2	D1/D2
2006-2007	D3	D3
2008-2017	D3 + CO	D3 + CO

EPCWID Operations		
Charge EPCWID for Use of WWTP Returns	Off	Off
ACE and Haskell Credits for EPCWID	On	On
Increased EPCWID Use of Fabens Drain Flows	Off	Off
Charge EPCWID for Fabens Drain Flow Use	Off	Off

Run 4 - TX Pumping Off
Comparison of ILRG Model Runs
Run 4 v. Run 1
1951 - 2017 Annual Average
(1,000 acre-feet)

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 4 - TX Pumping Off

Simulated Differences in ILRG Model Outputs

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

1985-2017	990	1,802	-30
1985-2005	189	1,615	0

Notes:

(1) EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

(2) EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

(3) HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

(4) EPCWID FHG values include deliveries to Rogers WTP and R/U WTP.

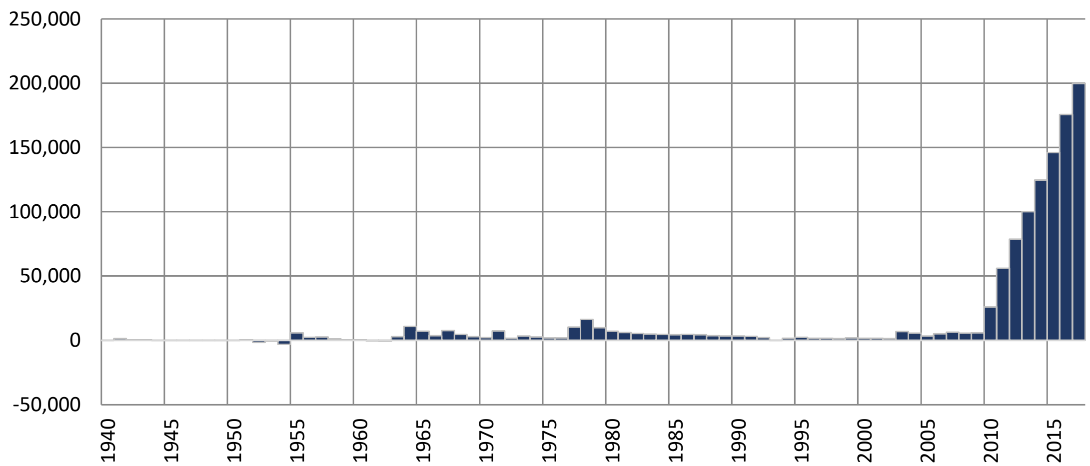
Run 5 - MX Pumping Off

Simulated Differences in ILRG Model Outputs

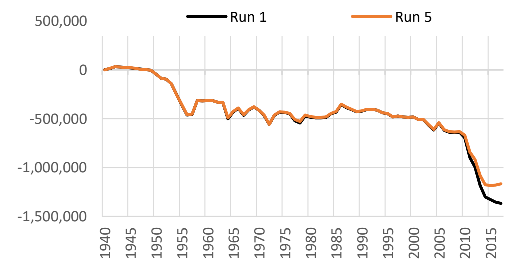
Run 5 minus Run 1

1940 - 2017 (acre-feet)

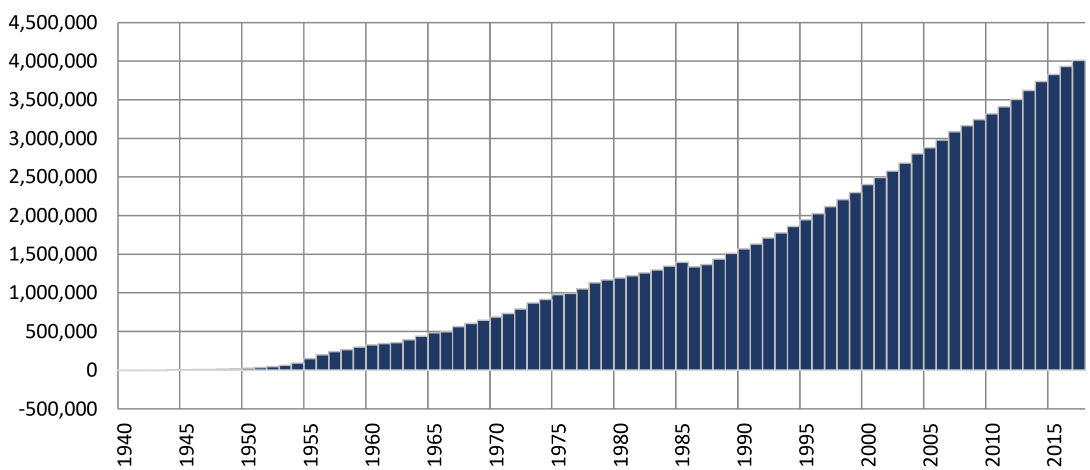
Cumulative Annual Rincon-Mesilla Groundwater Storage



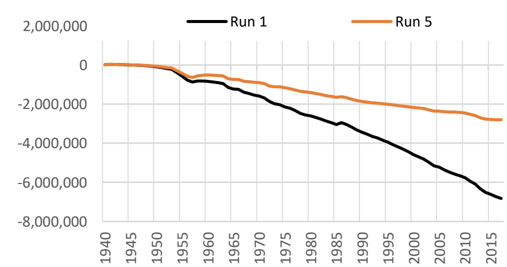
Period	Average Difference
1951-2017	2,980
1951-1978	584
1979-2005	-477
2006-2017	16,348
1985-2017	5,907
1985-2005	-60



Cumulative Annual Hueco Groundwater Storage



Period	Average Difference
1951-2017	59,524
1951-1978	39,524
1979-2005	64,726
2006-2017	94,489
1985-2017	80,745
1985-2005	72,892



Notes:

Cumulative storage change in alluvial and non-alluvial aquifers.

Average differences calculated as (Final Storage - Initial Storage)/(no. years).

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Note: HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 6 - RM Pumping Off
End of Month Reservoir Storage (Elephant Butte + Caballo)
Run 6 v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

Run 6 - RM Pumping Off
Monthly Caballo Releases
Run 6 v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

Run 6 - RM Pumping Off
Monthly Rio Grande at El Paso Flow
Run 6 v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

Run 6 - RM Pumping Off
Monthly Rio Grande at Fort Quitman Flow
Run 6 v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

Appendix 30G

Comparison of ILRG Model Runs
Run 7 v. Run 1

Model Run Specifications

Model Version: LRG_v116

Name: **Run 7 - TX Mesilla Pumping Off**

Run ID: LRG_v116_Operational_Run7
Date: 8/25/2020

Name: **Run 1 - Historical Base Run**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

Pumping and Returns	**Run 7**	**Run 1**
Irrigation Pumping	TX Mesilla Off	On
Irrigated Area	Hist	Hist
Non-Irrigation Pumping	TX Mesilla Off	On
Non-Irrigation Pumping Returns	TX Mesilla Off	On
Las Cruces Jornada Pumping Returns	On	On

Project Allocation Rules		
1950-2005	D1/D2	D1/D2
2006-2007	D3	D3
2008-2017	D3 + CO	D3 + CO

EPCWID Operations		
Charge EPCWID for Use of WWTP Returns	Off	Off
ACE and Haskell Credits for EPCWID	On	On
Increased EPCWID Use of Fabens Drain Flows	Off	Off
Charge EPCWID for Fabens Drain Flow Use	Off	Off

Run 7 - TX Mesilla Pumping Off

Comparison of ILRG Model Runs

Run 7 v. Run 1

1951 - 2017 Annual Average

(1,000 acre-feet)

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 7 - TX Mesilla Pumping Off

Simulated Differences in ILRG Model Outputs

Run 7 minus Run 1

1940 - 2017 (acre-feet)

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

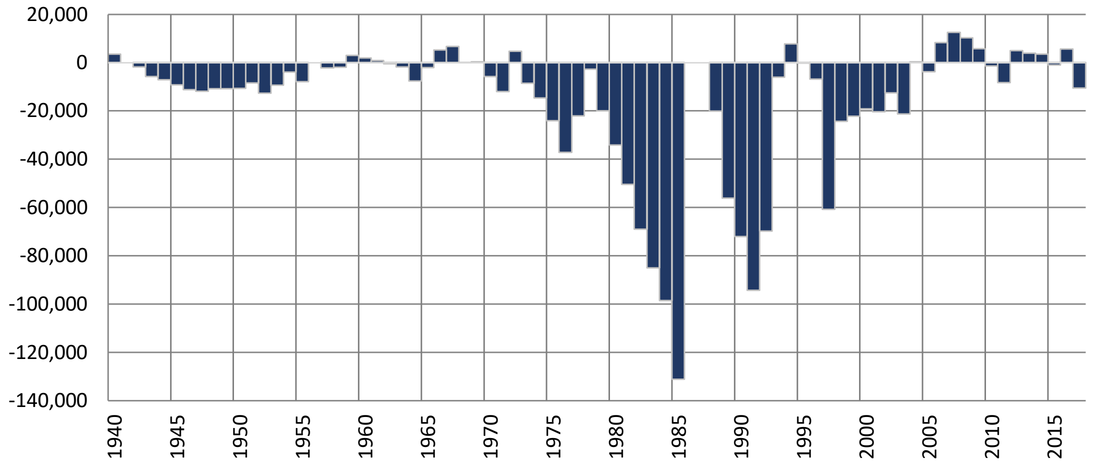
Run 8 - TX Non-Irrigation Pumping Off

Simulated Differences in ILRG Model Outputs

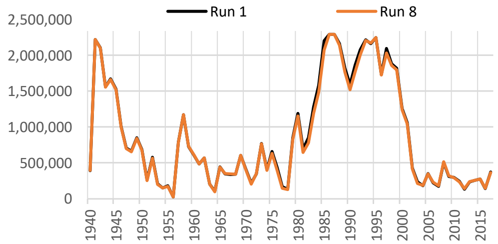
Run 8 minus Run 1

1940 - 2017 (acre-feet)

Total Project Storage (Year End)

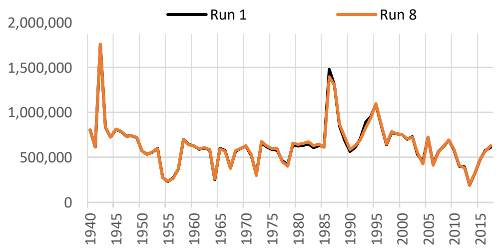


Period	Average Difference
1951-2017	1
1951-1978	284
1979-2005	-44
2006-2017	-558
1985-2017	2,669
1985-2005	4,514



Caballo Reservoir Outflows (Annual)

	Average Difference		
Period	Irr Season (excl. Spills)	Nov-Feb and Spills	Annual
1951-2017	9,918	-8,394	1,524
1951-1978	583	0	583
1979-2005	23,510	-20,829	2,681
2006-2017	1,117	0	1,117
1985-2017	15,912	-17,042	-1,130
1985-2005	24,366	-26,780	-2,414



Notes:

Reservoir storage does not include storage attributed to SJC, CO, or NM credit waters.

Average differences calculated as (Final Storage - Initial Storage)/(no. years).

Run 8 - TX Non-Irrigation Pumping Off

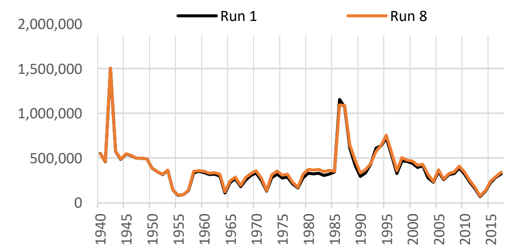
Simulated Differences in ILRG Model Outputs

Run 8 minus Run 1

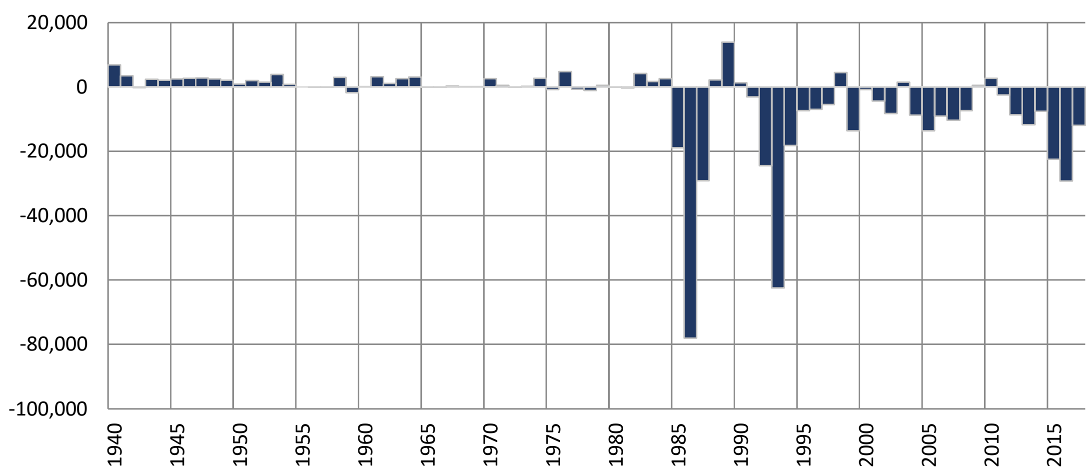
1940 - 2017 (acre-feet)

Rio Grande at El Paso (Annual)

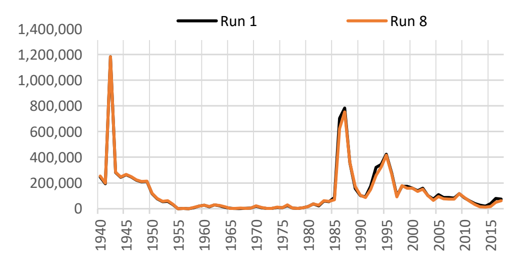
	Average Difference		
Period	Irr Season (excl. Spills)	Nov-Feb and Spills	Annual
1951-2017	18,903	-729	18,173
1951-1978	12,709	2,845	15,555
1979-2005	29,303	-6,621	22,682
2006-2017	9,951	4,187	14,138
1985-2017	21,190	-4,921	16,269
1985-2005	27,612	-10,125	17,486



Rio Grande at Fort Quitman (Annual)



Period	Average Difference
1951-2017	-5,420
1951-1978	960
1979-2005	-10,081
2006-2017	-9,820
1985-2017	-12,075
1985-2005	-13,363



Run 8 - TX Non-Irrigation Pumping Off

Simulated Differences in ILRG Model Outputs

Run 8 minus Run 1

1940 - 2017 (acre-feet)

River Headgate (RHG) Diversions (Irrigation Season)

	Average Difference		
Period	EBID	EPCWID	HCCRD
1951-2017	411	7,063	708
1951-1978	-2,928	2,475	839
1979-2005	-1,314	14,269	1,849
2006-2017	12,081	1,555	-2,165
1985-2017	3,409	8,427	235
1985-2005	-1,546	12,354	1,606

Farm Headgate (FHG) Deliveries (Irrigation Season)

	Average Difference		
Period	EBID	EPCWID	HCCRD
1951-2017	1,506	-2,244	49
1951-1978	-974	-2,522	276
1979-2005	1,390	-734	33
2006-2017	7,555	-4,993	-445
1985-2017	3,687	-2,300	-162
1985-2005	1,477	-762	0

Notes:

(1) EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

(2) EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

(3) HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

(4) EPCWID FHG values include deliveries to Rogers WTP and R/U WTP.

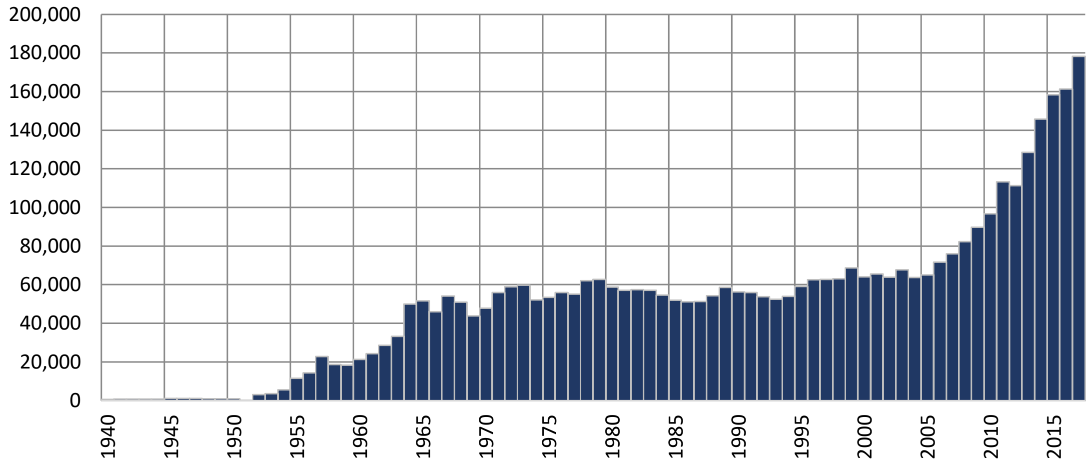
Run 8 - TX Non-Irrigation Pumping Off

Simulated Differences in ILRG Model Outputs

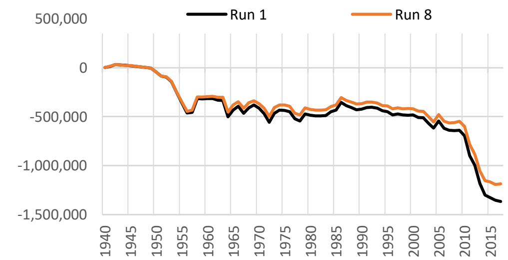
Run 8 minus Run 1

1940 - 2017 (acre-feet)

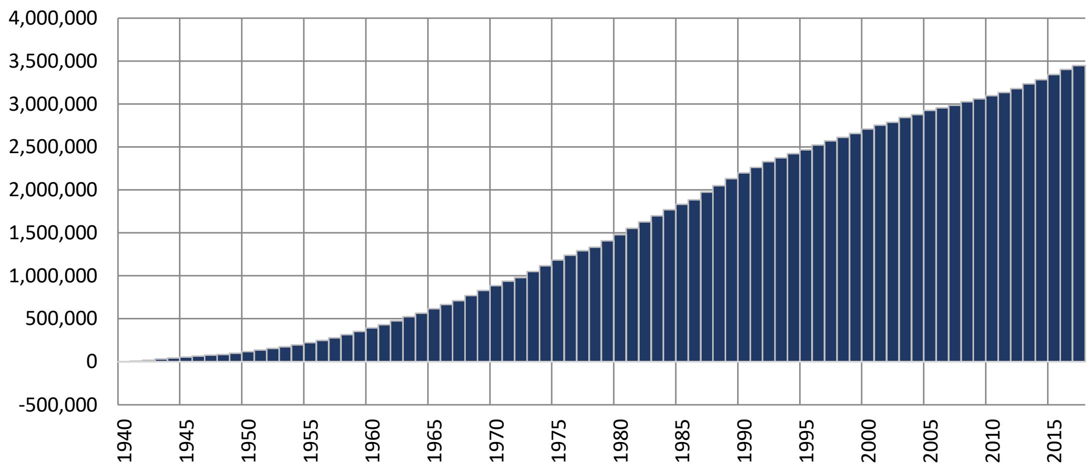
Cumulative Annual Rincon-Mesilla Groundwater Storage



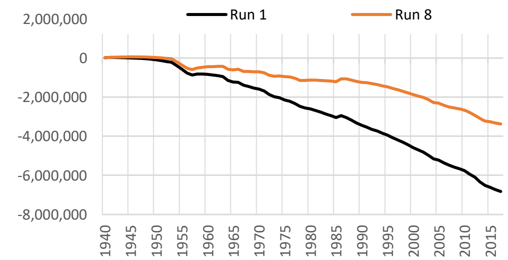
Period	Average Difference
1951-2017	2,646
1951-1978	2,181
1979-2005	109
2006-2017	9,437
1985-2017	3,746
1985-2005	494



Cumulative Annual Hueco Groundwater Storage



Period	Average Difference
1951-2017	49,740
1951-1978	43,453
1979-2005	58,901
2006-2017	43,793
1985-2017	50,923
1985-2005	54,998



Notes:

Cumulative storage change in alluvial and non-alluvial aquifers.

Average differences calculated as (Final Storage - Initial Storage)/(no. years).

Run 8 - TX Non-Irrigation Pumping Off

Comparison of ILRG Model Runs
Run 9 v. Run 1

Model Run Specifications

Model Version: LRG_v116

Name: **Run 9 - NM Non-Irrigation Pumping Off**

Run ID: LRG_v116_Operational_Run9
Date: 8/26/2020

Name: **Run 1 - Historical Base Run**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

Pumping and Returns	Run 9	Run 1
Irrigation Pumping	On	On
Irrigated Area	Hist	Hist
Non-Irrigation Pumping	NM Off	On
Non-Irrigation Pumping Returns	NM Off	On
Las Cruces Jornada Pumping Returns	Off	On

Project Allocation Rules		
1950-2005	D1/D2	D1/D2
2006-2007	D3	D3
2008-2017	D3 + CO	D3 + CO

EPCWID Operations		
Charge EPCWID for Use of WWTP Returns	Off	Off
ACE and Haskell Credits for EPCWID	On	On
Increased EPCWID Use of Fabens Drain Flows	Off	Off
Charge EPCWID for Fabens Drain Flow Use	Off	Off

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

1951-2017			
1951-1978			
1979-2005			
2006-2017	54,568	-17,179	-1,035
1985-2017			
1985-2005			

Notes:

(1) EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

(2) EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

(3) HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

(4) EPCWID FHG values include deliveries to Rogers WTP and R/U WTP.

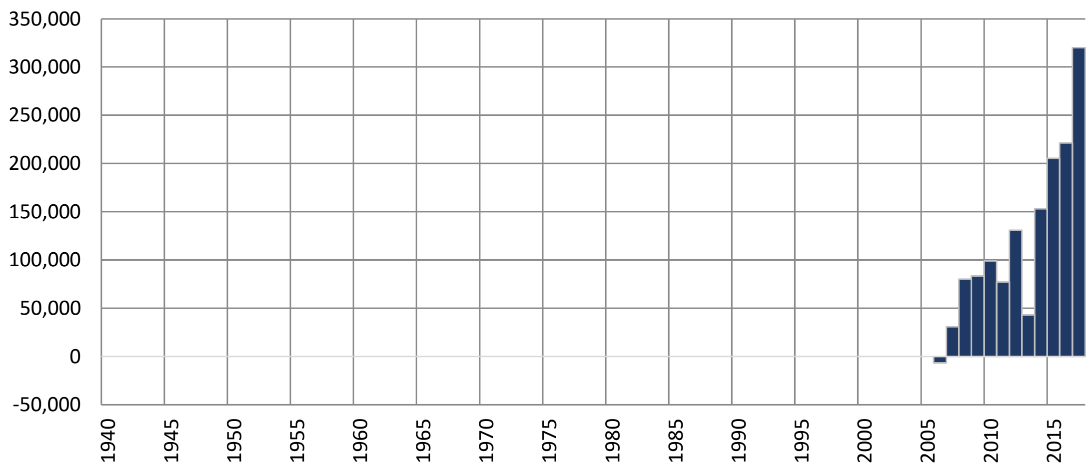
Run 11 - D1/D2

Simulated Differences in ILRG Model Outputs

Run 11 minus Run 1

1940 - 2017 (acre-feet)

Cumulative Annual Rincon-Mesilla Groundwater Storage



Period	Average Difference
1951-2017	
1951-1978	
1979-2005	
2006-2017	26,667
1985-2017	
1985-2005

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

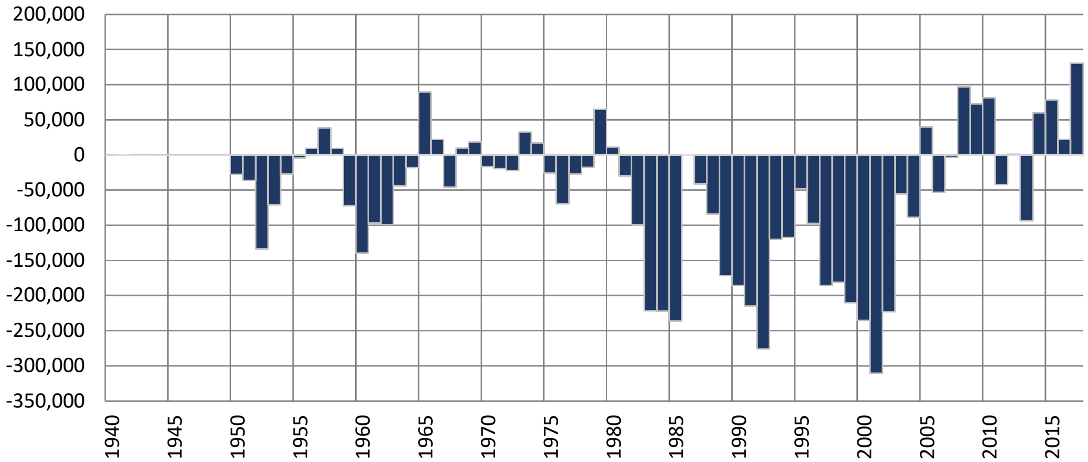
Run 12 - D3 + Carryover Allocation (All Pumping On)

Simulated Differences in ILRG Model Outputs

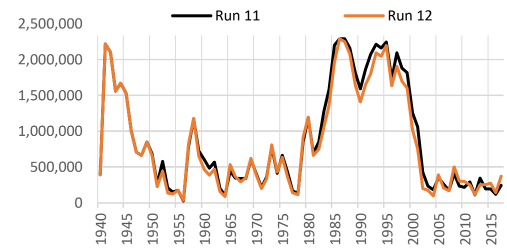
Run 12 minus Run 11

1940 - 2017 (acre-feet)

Total Project Storage (Year End)



Period	Average Difference
1951-2017	2,357
1951-1978	356
1979-2005	2,125
2006-2017	7,550
1985-2017	10,688
1985-2005	12,482



Caballo Reservoir Outflows (Annual)

	Average Difference		
Period	Irr Season (excl. Spills)	Nov-Feb and Spills	Annual

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Irrigation Season Summary of Irrigation Operations
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

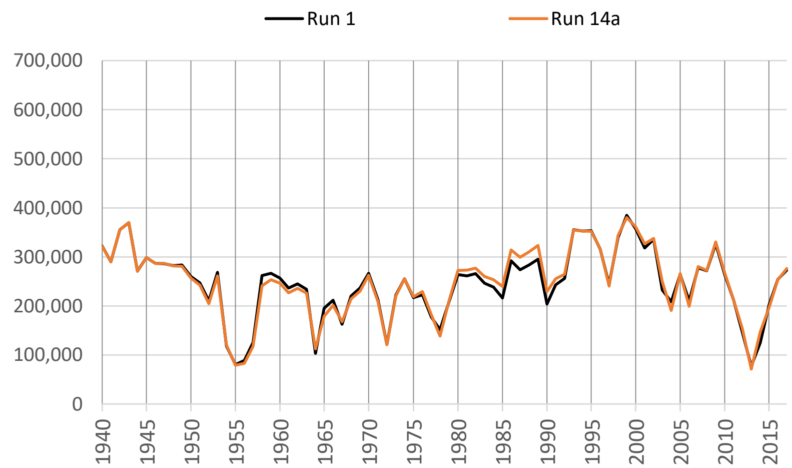
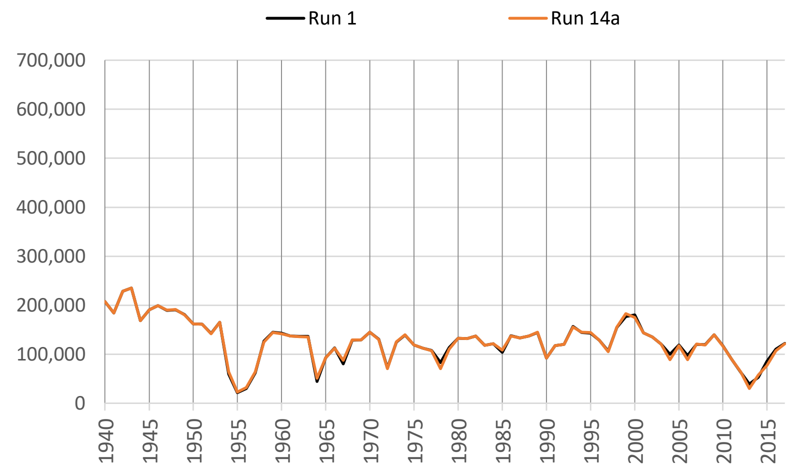
EPCWID Total

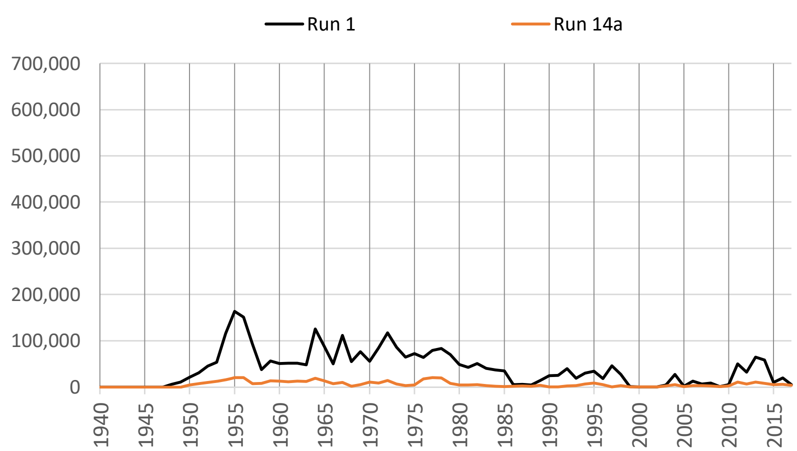
Net River Headgate Diversions



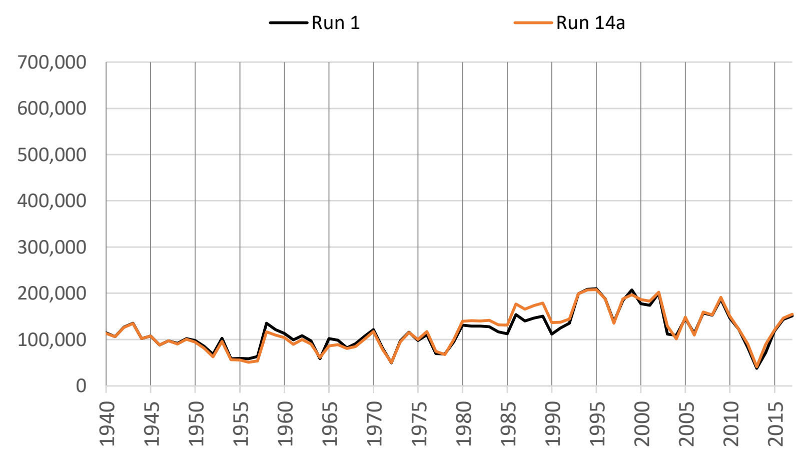
Farm Headgate Deliveries



Pumping



RHG Diversions - FHG Deliveries



Note: EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

Run 14a - TX Hueco Pumping Off
Irrigation Season Summary of Irrigation Operations
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

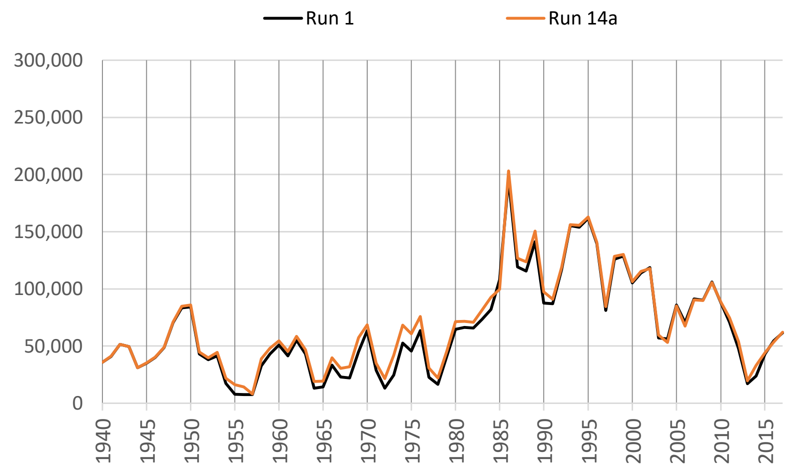
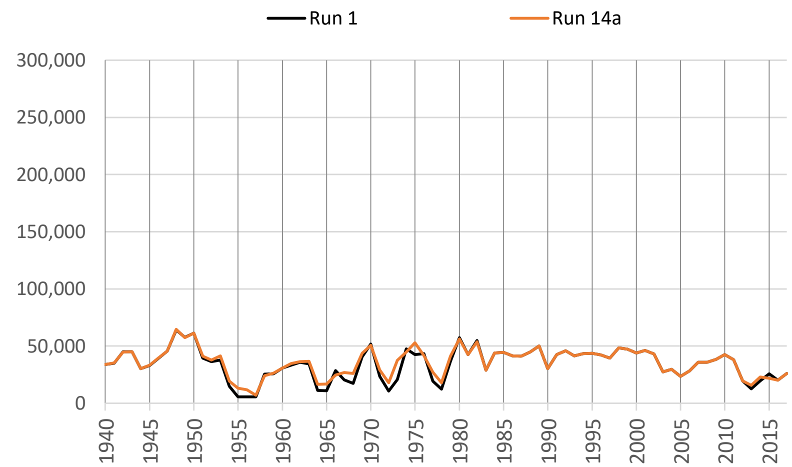
HCCRD Total

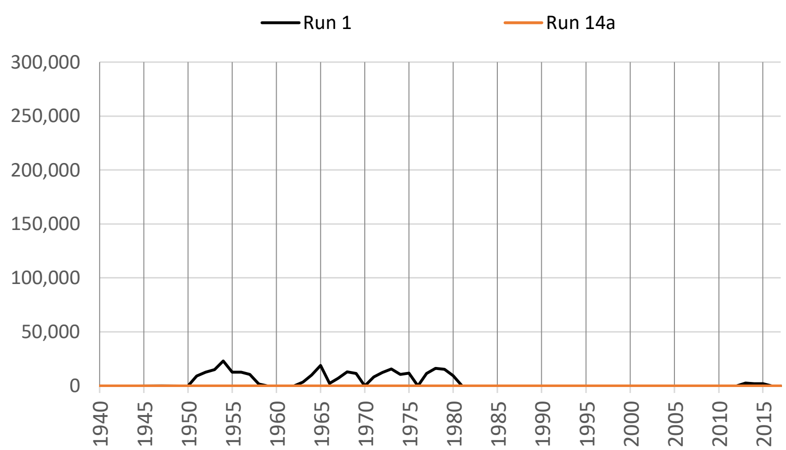
Net River Headgate Diversions



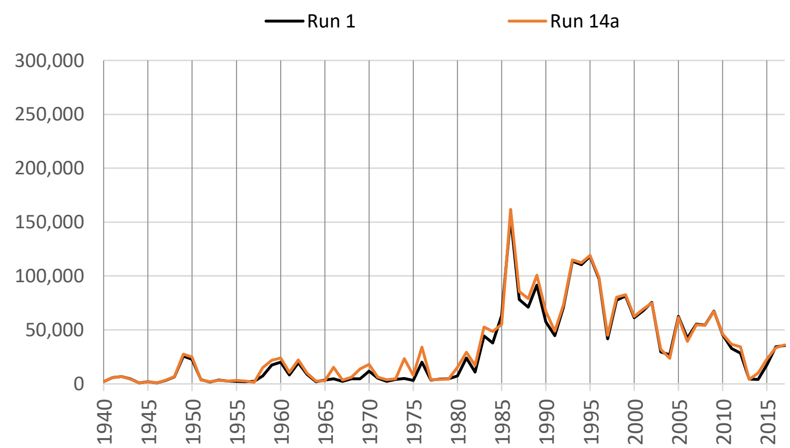
Farm Headgate Deliveries



Pumping



RHG Diversions - FHG Deliveries



Note: HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 14a - TX Hueco Pumping Off
Cumulative Change in Ground Water Storage
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

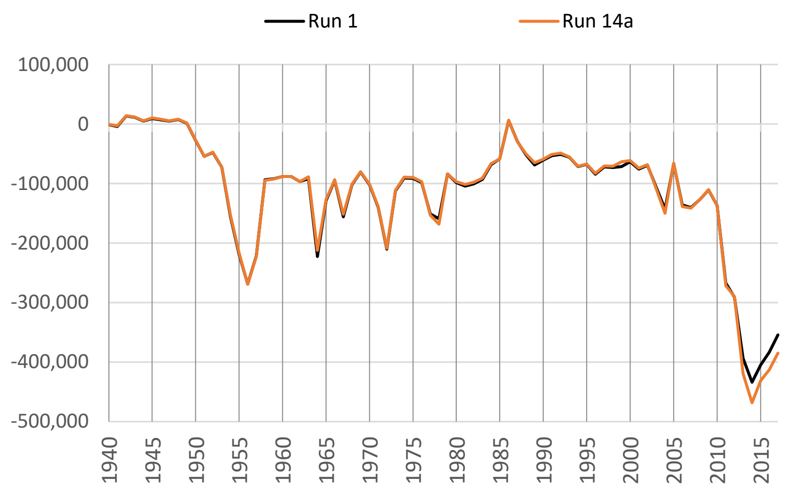
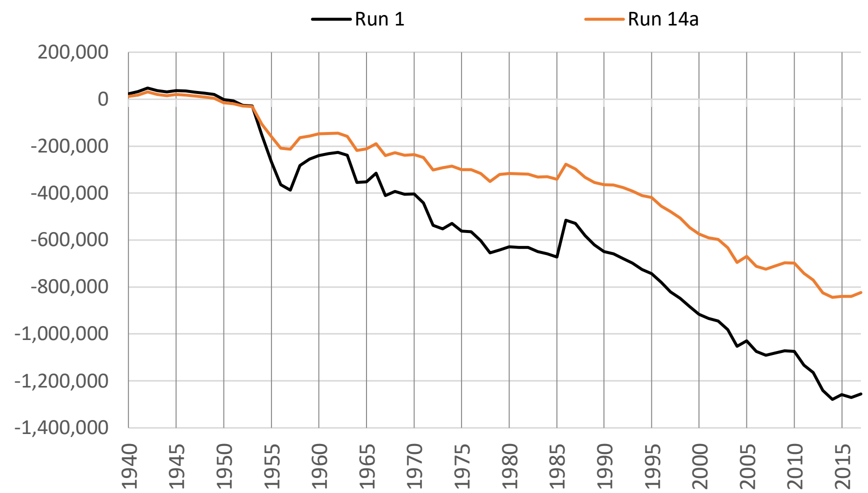
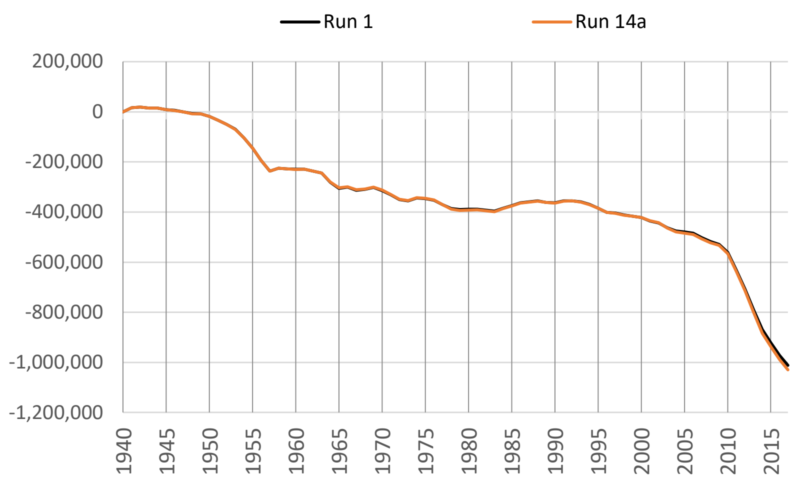
Rincon-Mesilla Alluvial Aquifer



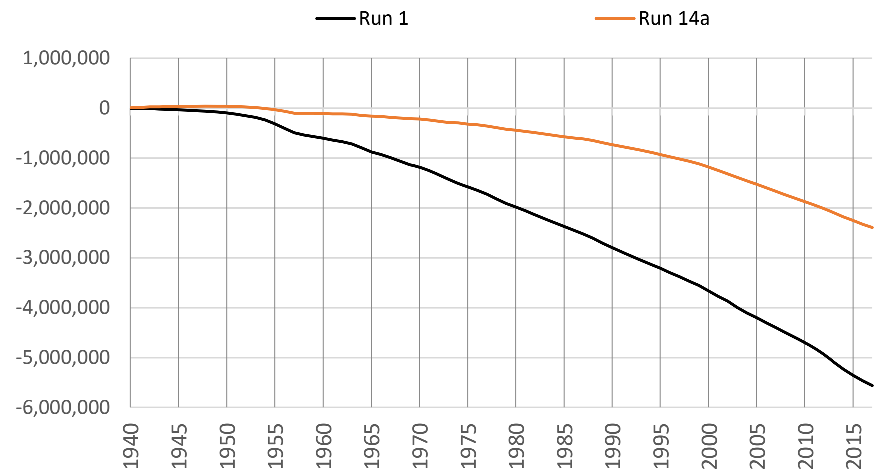
Hueco Alluvial Aquifer



Rincon-Mesilla Non-Alluvial Aquifer



Hueco Non-Alluvial Aquifer



***Note different scales.**

Run 14a - TX Hueco Pumping Off
Monthly Net RHG Diversions
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)
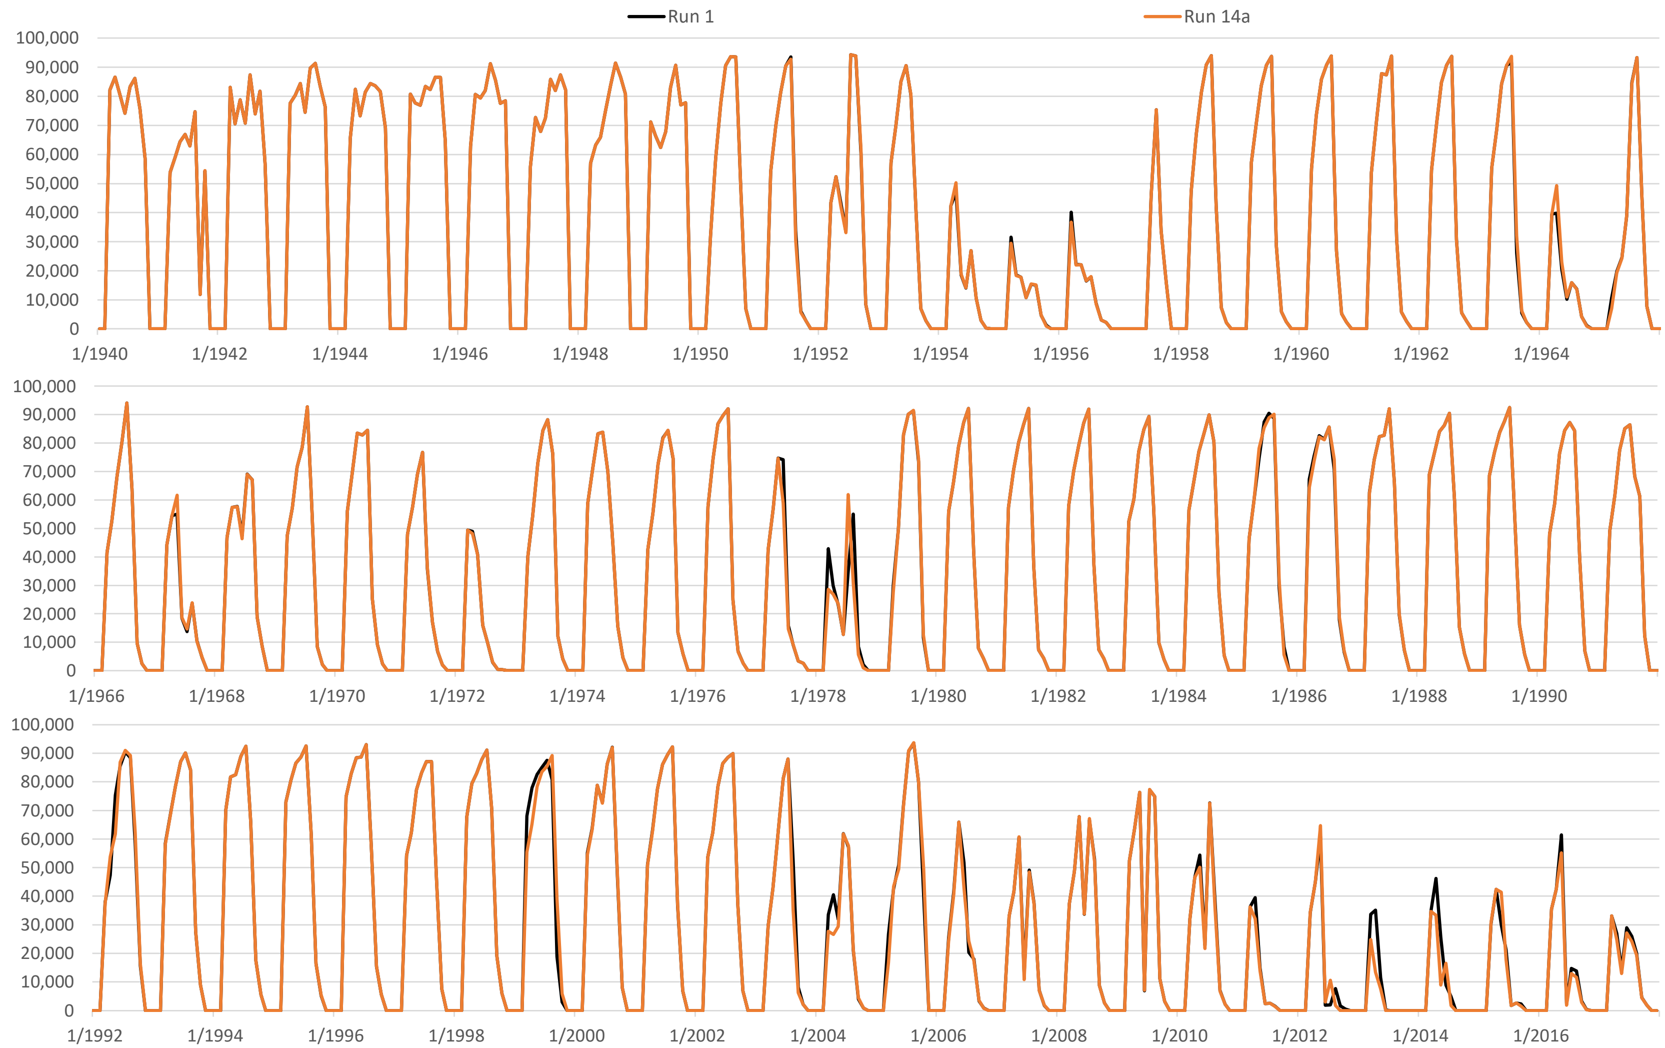
EBID Total



Note: EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

Run 14a - TX Hueco Pumping Off
Monthly Net RHG Diversions
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)
EPCWID Total

Note: EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

Run 14a - TX Hueco Pumping Off
Monthly Net RHG Diversions
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)
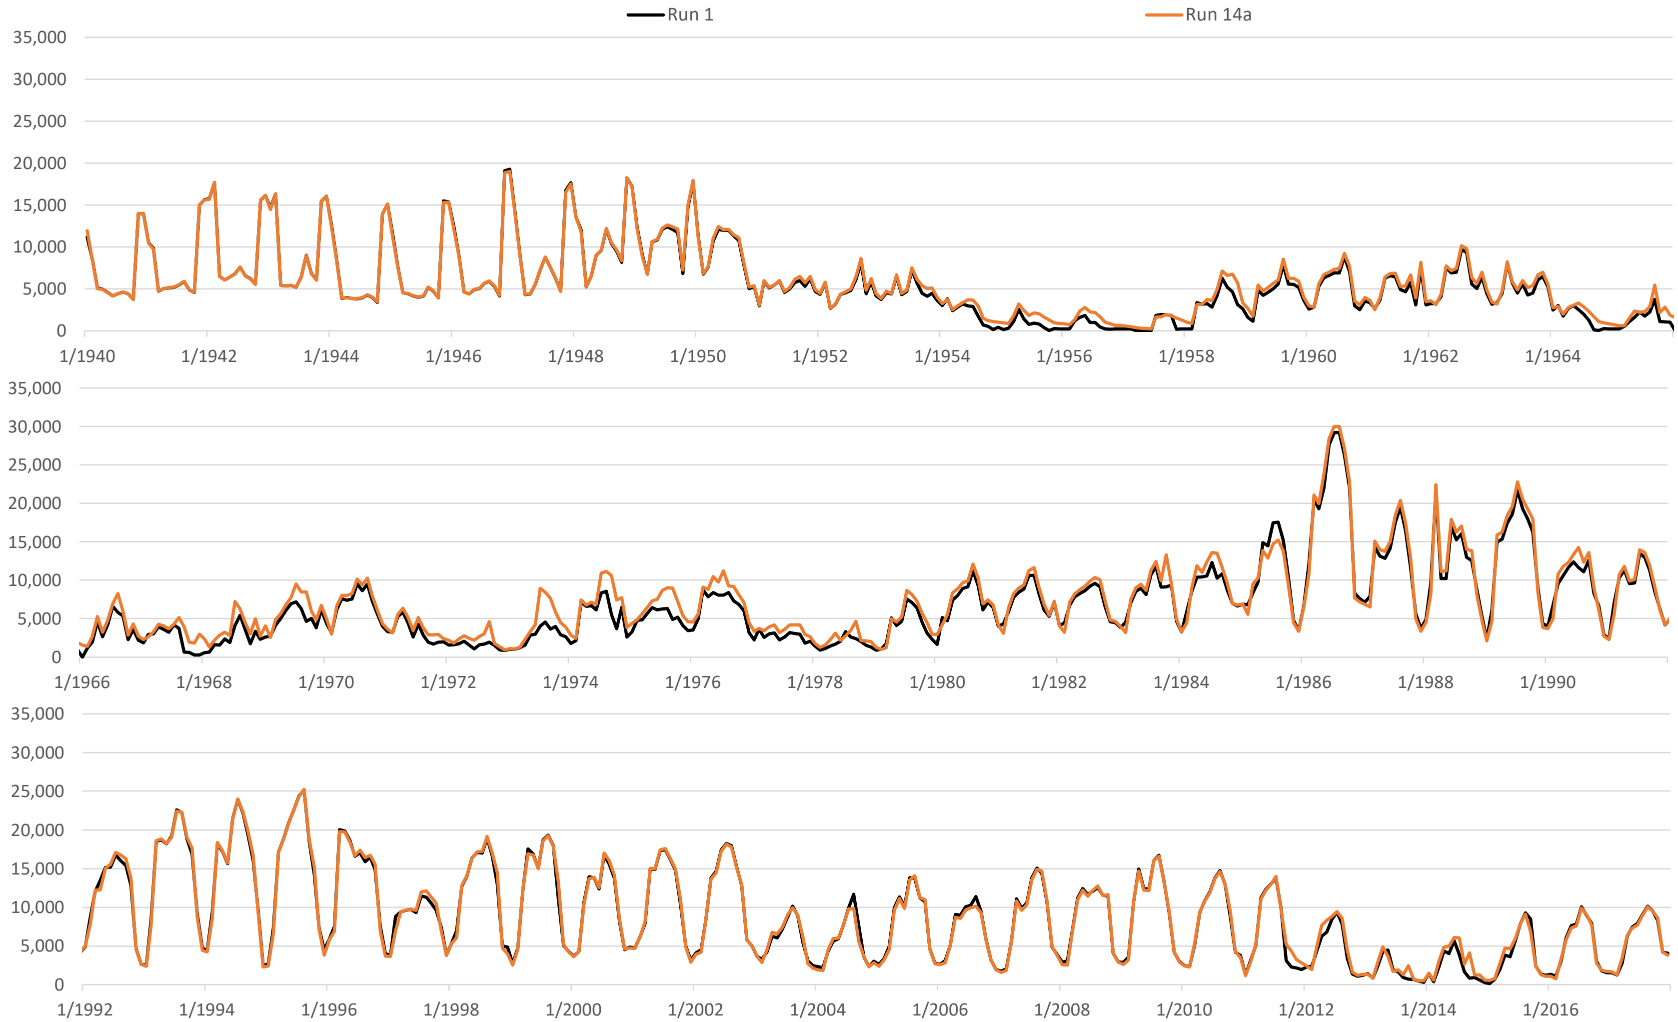
HCCRD Total



Note: HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 14a - TX Hueco Pumping Off
End of Month Reservoir Storage (Elephant Butte + Caballo)
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

Run 14a - TX Hueco Pumping Off

Monthly Caballo Releases

Run 14a v. Run 1

ILRG Model

1940 - 2017 (acre-feet)

Run 14a - TX Hueco Pumping Off
Monthly Rio Grande at El Paso Flow
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

Run 14a - TX Hueco Pumping Off
Monthly Rio Grande at Fort Quitman Flow
Run 14a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

Appendix 30P

Comparison of ILRG Model Runs
Run 14b v. Run 1

Model Run Specifications

Model Version: LRG_v116

Name: **Run 14b - MX Hueco Pumping Off**

Run ID: LRG_v116_Operational_Run14b
Date: 8/24/2020

Name: **Run 1 - Historical Base Run (All Pumping On)**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

Pumping and Returns	Run 14b	Run 1
Irrigation Pumping	MX Hueco Off	On
Irrigated Area	Hist	Hist
Non-Irrigation Pumping	MX Hueco Off	On
Non-Irrigation Pumping Returns	MX Hueco Off	On
Las Cruces Jornada Pumping Returns	On	On

Project Allocation Rules		
1950-2005	D1/D2	D1/D2
2006-2007	D3	D3
2008-2017	D3 + CO	D3 + CO

EPCWID Operations		
Charge EPCWID for Use of WWTP Returns	Off	Off
ACE and Haskell Credits for EPCWID	On	On
Increased EPCWID Use of Fabens Drain Flows	Off	Off
Charge EPCWID for Fabens Drain Flow Use	Off	Off

Run 14b - MX Hueco Pumping Off
Comparison of ILRG Model Runs
Run 14b v. Run 1
1951 - 2017 Annual Average

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

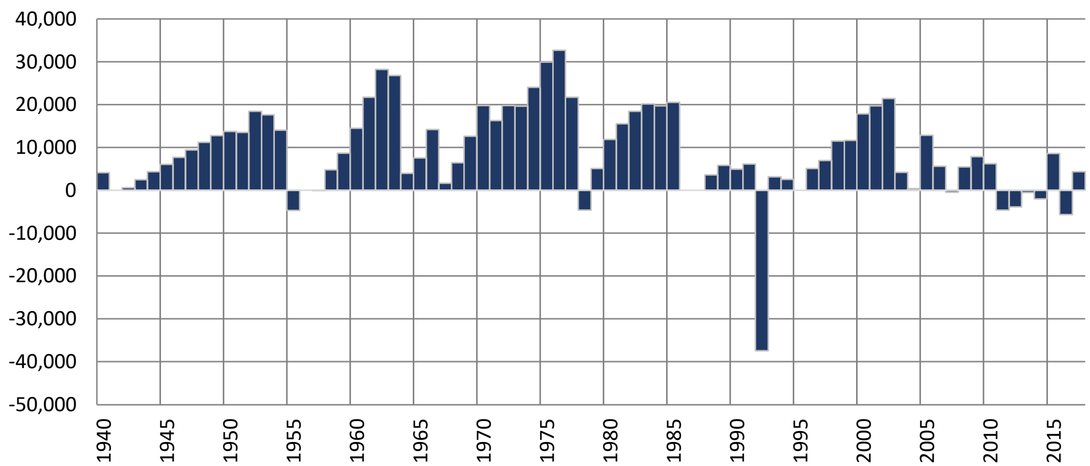
Run 14b - MX Hueco Pumping Off

Simulated Differences in ILRG Model Outputs

Run 14b minus Run 1

1940 - 2017 (acre-feet)

Total Project Storage (Year End)



Period	Average Difference
1951-2017	-141
1951-1978	-657
1979-2005	647
2006-2017	-709
1985-2017	-467

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

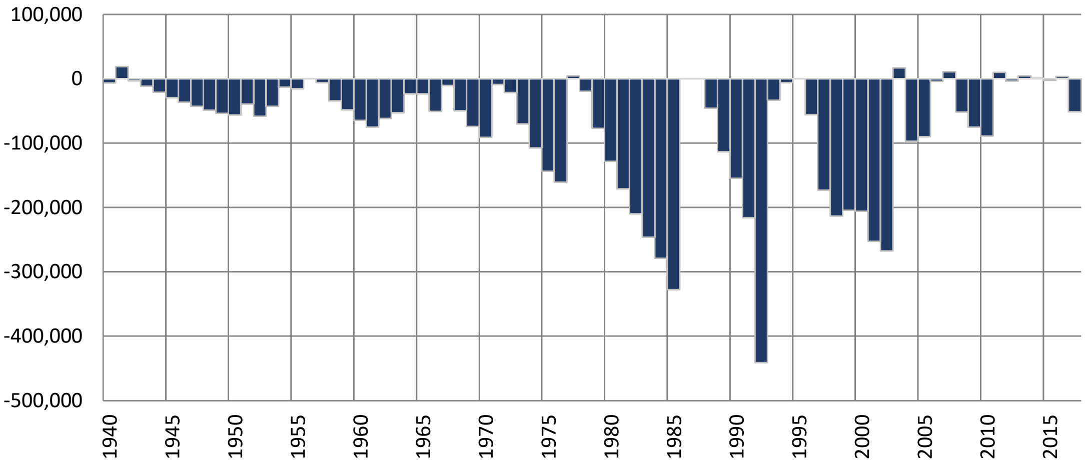
Run 14c - TX WWTP Discharges Off

Simulated Differences in ILRG Model Outputs

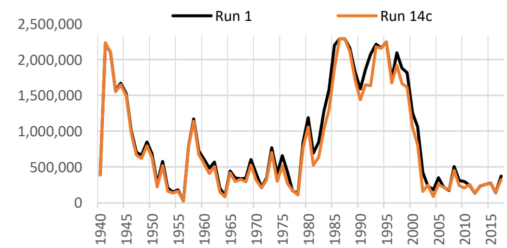
Run 14c minus Run 1

1940 - 2017 (acre-feet)

Total Project Storage (Year End)



Period	Average Difference
1951-2017	69
1951-1978	1,312
1979-2005	-2,609
2006-2017	3,195
1985-2017	6,888
1985-2005	8,998



Caballo Reservoir Outflows (Annual)

	Average Difference		
Period	Irr Season (excl. Spills)	Nov-Feb and Spills	Annual
1951-2017	25,155	-18,695	6,460
1951-1978	4,812	0	4,812
1979-2005	56,782	-46,391	10,391
2006-2017	1,460	0	1,460

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 14d - TX Hueco Pumping Off (Returns Left On)

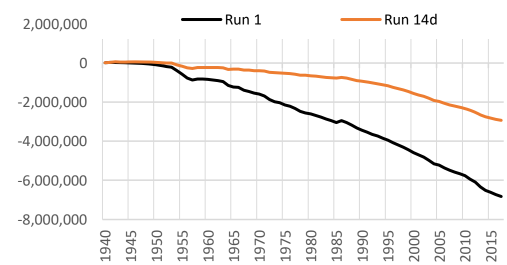
2006-2017	51,440
1985-2017	50,989
1985-2005	50,731



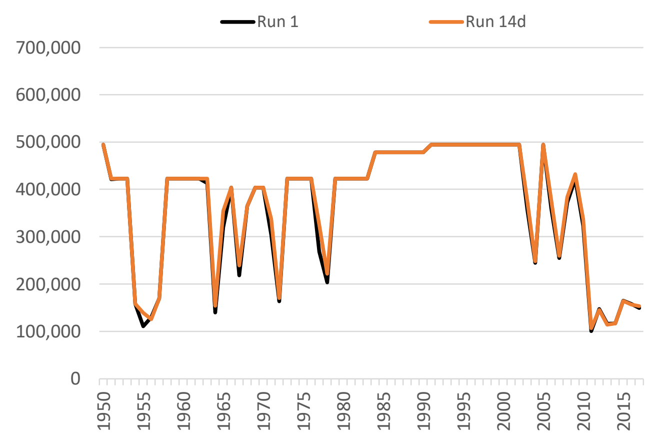
Notes:

Cumulative storage change in alluvial and non-alluvial aquifers.

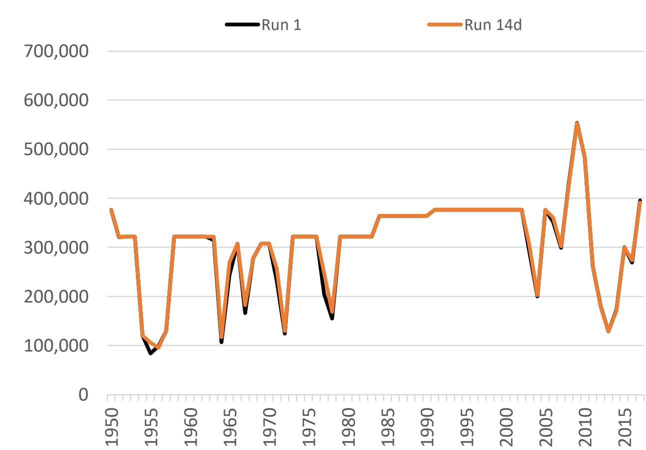
Average differences calculated as (Final Storage - Initial Storage)/(no. years).

Run 14d - TX Hueco Pumping Off (Returns Left On)
Annual Allocation and Charges
Run 14d v. Run 1
ILRG Model
1950 - 2017 (acre-feet)

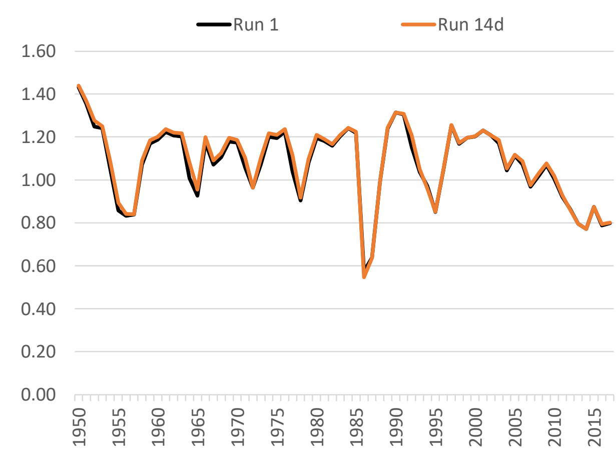
Total Allocation - EBID



Total Allocation - EPCWID

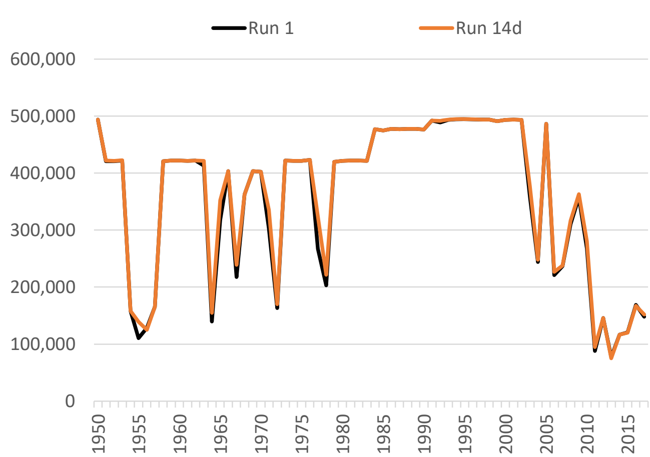


Diversion Ratio



Note:
Computed as Total Charges/Caballo Release.

Annual Delivery Charges - EBID



Annual Delivery Charges - EPCWID

Appendix 30S

Comparison of ILRG Model Runs
Run 15 v. Run 1

Model Run Specifications

Model Version: LRG_v116

Name: **Run 15 - Early EPCWID Ops (WWTP & Fabens Drain)**

Run ID: LRG_v116_Operational_Run15
Date: 8/27/2020

Name: **Run 1 - Historical Base Run (All Pumping On)**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

Pumping and Returns	Run 15	Run 1
Irrigation Pumping	On	On
Irrigated Area	Hist	Hist
Non-Irrigation Pumping	On	On
Non-Irrigation Pumping Returns	On	On
Las Cruces Jornada Pumping Returns	On	On

Project Allocation Rules		
1950-2005	D1/D2	D1/D2
2006-2007	D3	D3
2008-2017	D3 + CO	D3 + CO

EPCWID Operations		
Charge EPCWID for Use of WWTP Returns	On	Off
ACE and Haskell Credits for EPCWID	Off	On
(1) Increased EPCWID Use of Fabens Drain Flows	On	Off
Charge EPCWID for Fabens Drain Flow Use	On	Off

Notes:
(1) Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 af/month.

Run 15 - Early EPCWID Ops (WWTP & Fabens Drain)

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 15 - Early EPCWID Ops (WWTP & Fabens Drain)

Simulated Differences in ILRG Model Outputs

Run 15 minus Run 1

1940 - 2017 (acre-feet)

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

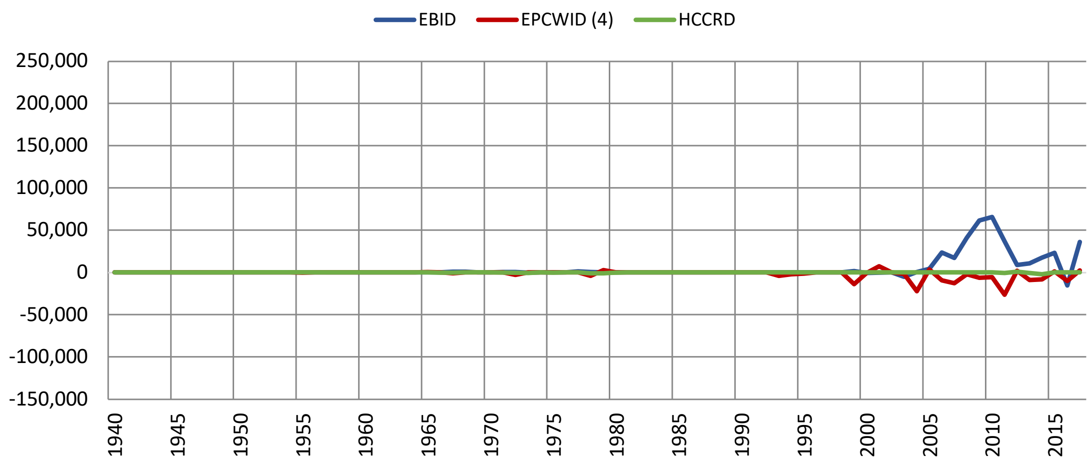
1985-2005	-552	-3,153	-632

Farm Headgate (FHG) Deliveries (Irrigation Season)



Period	Average Difference EBID	EPCWID	HCCRD
1951-2017	4,960	-1,852	-95
1951-1978	153	-269	-91
1979-2005	76	-1,200	-44
2006-2017	27,166	-7,013	-219
1985-2017	9,932	-3,615	-80
1985-2005	83	-1,673	0

Notes:

(1) EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

(2) EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

(3) HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

(4) EPCWID FHG values include deliveries to Rogers WTP and R/U WTP.

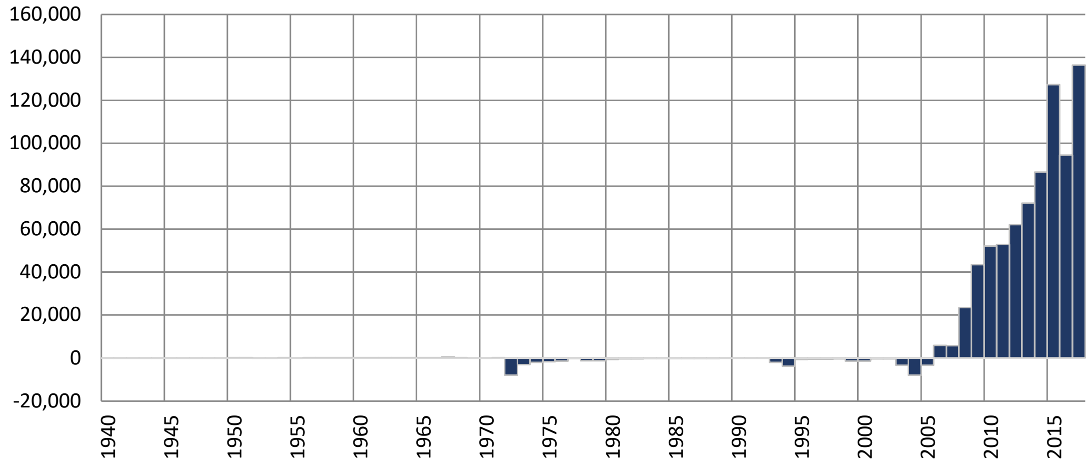
Run 15a - Early EPCWID Ops (WWTP)

Simulated Differences in ILRG Model Outputs

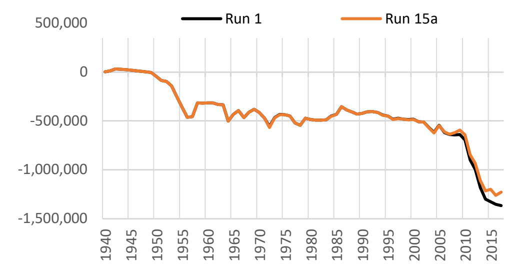
Run 15a minus Run 1

1940 - 2017 (acre-feet)

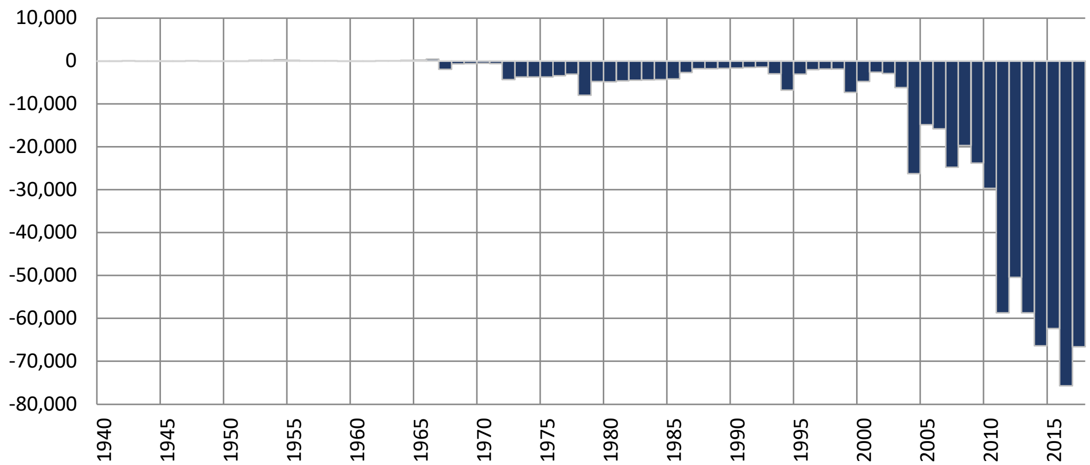
Cumulative Annual Rincon-Mesilla Groundwater Storage



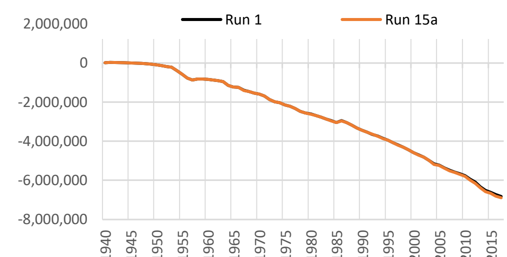
Period	Average Difference
1951-2017	2,036
1951-1978	-47
1979-2005	-77
2006-2017	11,650
1985-2017	4,143
1985-2005	-147



Cumulative Annual Hueco Groundwater Storage



Period	Average Difference
1951-2017	-994
1951-1978	-285
1979-2005	-252
2006-2017	-4,315
1985-2017	-1,888
1985-2005	-501



Notes:

Cumulative storage change in alluvial and non-alluvial aquifers.

Average differences calculated as (Final Storage - Initial Storage)/(no. years).

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

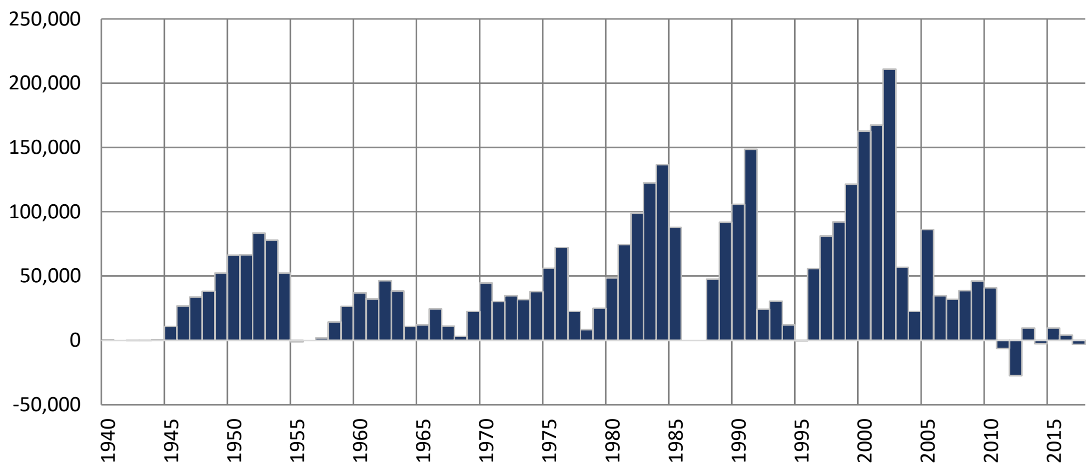
Run 15b - Early EPCWID Ops (Fabens Drain)

Simulated Differences in ILRG Model Outputs

Run 15b minus Run 1

1940 - 2017 (acre-feet)

Total Project Storage (Year End)



Period	Average Difference
1951-2017	-1,032
1951-1978	-2,067

Comparison of ILRG Model Runs
Run 15c v. Run 15

Model Run Specifications

Model Version: LRG_v116

Name: **Run 15c - Early EPCWID Ops (TX Hueco Pumping Off)**

Run ID: LRG_v116_Operational_Run15c
Date: 8/28/2020

Name: **Run 15 - Early EPCWID Ops (WWTP & Fabens Drains)**

Run ID: LRG_v116_Operational_Run15
Date: 8/27/2020

Selected Model Inputs

Pumping and Returns	**Run 15c**	**Run 15**
Irrigation Pumping	TX Hueco Off	On
Irrigated Area	Hist	Hist
Non-Irrigation Pumping	TX Hueco Off	On
Non-Irrigation Pumping Returns	TX Hueco Off	On
Las Cruces Jornada Pumping Returns	On	On

Project Allocation Rules		
1950-2005	D1/D2	D1/D2
2006-2007	D3	D3
2008-2017	D3 + CO	D3 + CO

EPCWID Operations		
Charge EPCWID for Use of WWTP Returns	On	On
ACE and Haskell Credits for EPCWID	Off	Off
(1) Increased EPCWID Use of Fabens Drain Flows	On	On
Charge EPCWID for Fabens Drain Flow Use	On	On

Notes:
(1) Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 af/month.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

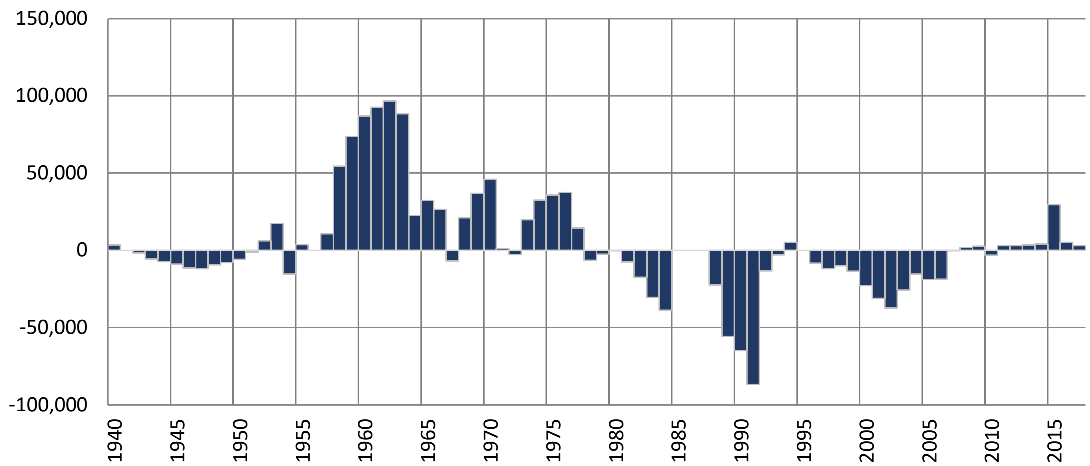
Run 15c - Early EPCWID Ops (TX Hueco Pumping Off)

Simulated Differences in ILRG Model Outputs

Run 15c minus Run 15

1940 - 2017 (acre-feet)

Total Project Storage (Year End)



Period	Average Difference
1951-2017	133
1951-1978	-27
1979-2005	-460
2006-2017	1,839
1985-2017	1,271

Model Run Specifications

Model Version: LRG_v116

Name: **Run 16 - Conj Use 1: Hist All Acres D1/D2 (Hist M&I)**

Run ID: LRG_v116_Operational_Run16
Date: 8/27/2020

Name: **Run 1 - Historical Base Run (All Pumping On)**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

	Pumping and Returns	Run 16	Run 1
(1)	Irrigation Pumping	1978 Limit	On
	Irrigated Area	Hist	Hist
	Non-Irrigation Pumping	On	On
	Non-Irrigation Pumping Returns	On	On
	Las Cruces Jornada Pumping Returns	Off	On
	Project Allocation Rules		
	1950-2005	D1/D2	D1/D2
	2006-2007	D1/D2	D3
	2008-2017	D1/D2	D3 + CO
	EPCWID Operations		
	Charge EPCWID for Use of WWTP Returns	On	Off
	ACE and Haskell Credits for EPCWID	Off	On
(2)	Increased EPCWID Use of Fabens Drain Flows	On	Off
	Charge EPCWID for Fabens Drain Flow Use	On	Off

Notes:

(1) Ten-year average irrigation pumping limited to 1951-1978 average:
EBID = 166,866 AF, EPCWID=70,783 AF, HCCRD = 11,188 AF.

(2) Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 AF/month.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Model Run Specifications

Model Version: LRG_v116

Name: **Run 16a - Conj Use 1a: Hist All Acres D1/D2 (1978 M&**

Run ID: LRG_v116_Operational_Run16a
Date: 8/28/2020

Name: **Run 1 - Historical Base Run (All Pumping On)**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

	Pumping and Returns	**Run 16a**	**Run 1**
(1)	Irrigation Pumping	1978 Limit	On
	Irrigated Area	Hist	Hist
(2)	Non-Irrigation Pumping	1978 Limit	On
	Non-Irrigation Pumping Returns	Reduced	On
	Las Cruces Jornada Pumping Returns	Off	On
	Project Allocation Rules		
	1950-2005	D1/D2	D1/D2
	2006-2007	D1/D2	D3
	2008-2017	D1/D2	D3 + CO
	EPCWID Operations		
	Charge EPCWID for Use of WWTP Returns	On	Off
	ACE and Haskell Credits for EPCWID	Off	On
(3)	Increased EPCWID Use of Fabens Drain Flows	On	Off
	Charge EPCWID for Fabens Drain Flow Use	On	Off

Notes:

(1) Ten-year average irrigation pumping limited to 1951-1978 average:
EBID = 166,866 AF, EPCWID=70,783 AF, HCCRD = 11,188 AF.

(2) Annual non-Irrigation pumping limited to 1951-1978 maximum: NM = 20,993 AF,
TX (Hueco) = 89,979 AF, TX (Mesilla) = 30,264 AF. Returns reduced based on pumping change.

(3) Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 AF/month.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

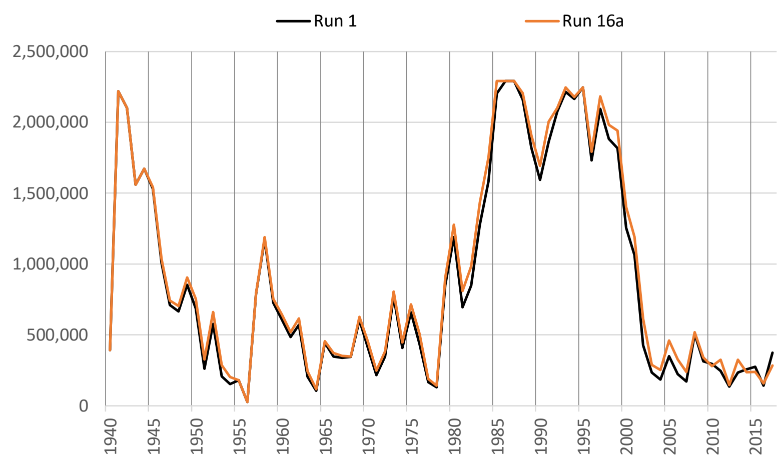
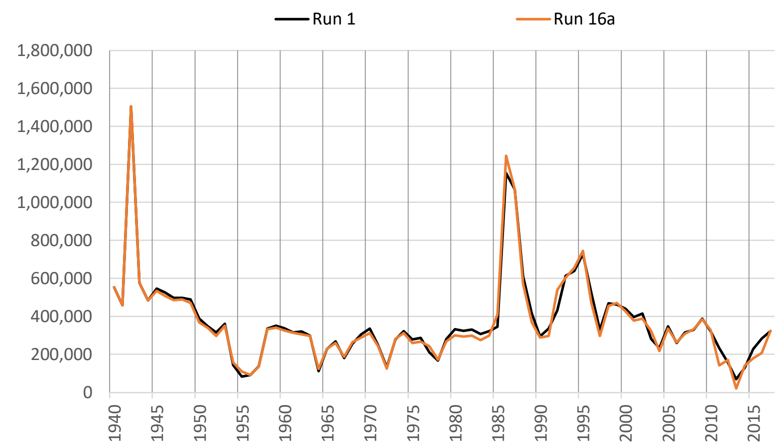
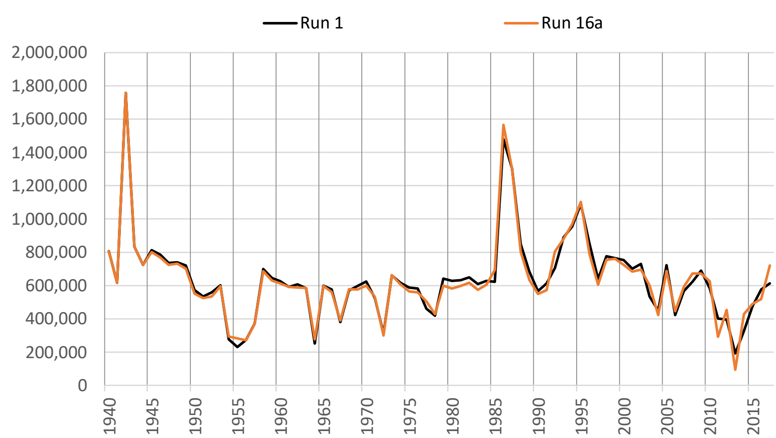
Total Year-End Project Reservoir Storage



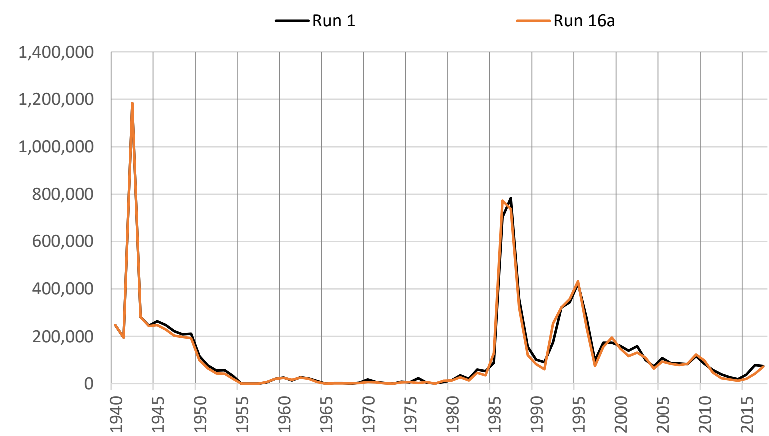
Rio Grande at El Paso



Rio Grande Below Caballo



Rio Grande at Fort Quitman

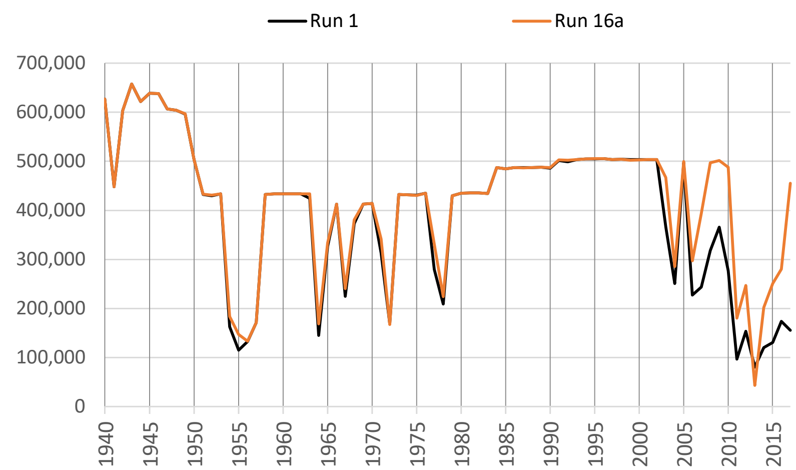


***Note different scales.**

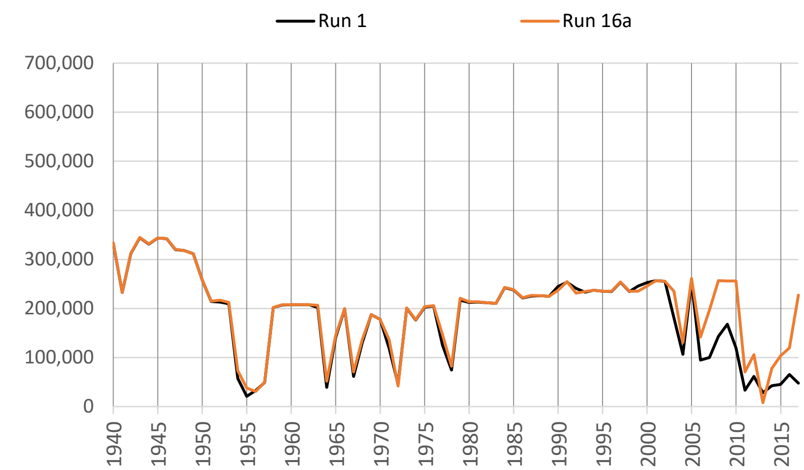
Run 16a - Conj Use 1a: Hist All Acres D1/D2 (1978 M&I)
Irrigation Season Summary of Irrigation Operations
Run 16a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

EBID Total

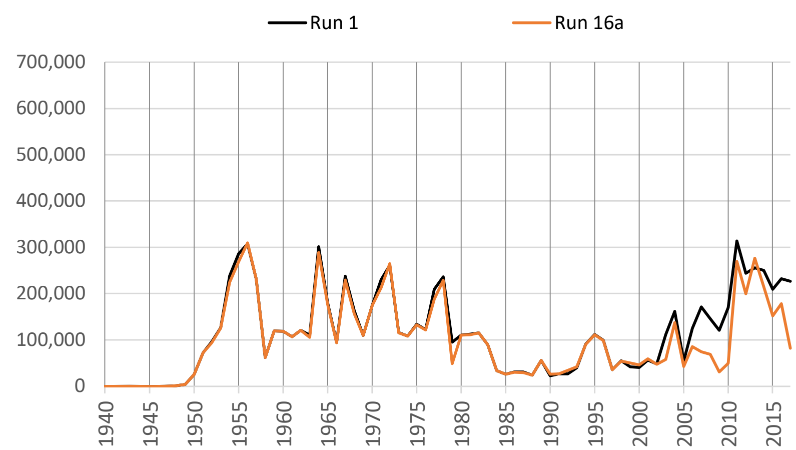
Net River Headgate Diversions



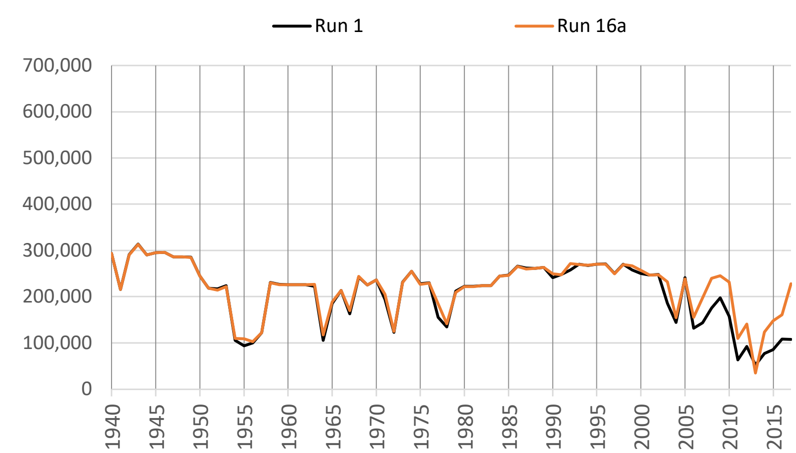
Farm Headgate Deliveries



Pumping



RHG Diversions - FHG Deliveries



Notes: EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).
Pumping includes Supplemental and Primary groundwater pumping.

Run 16a - Conj Use 1a: Hist All Acres D1/D2 (1978 M&I)

Irrigation Season Summary of Irrigation Operations

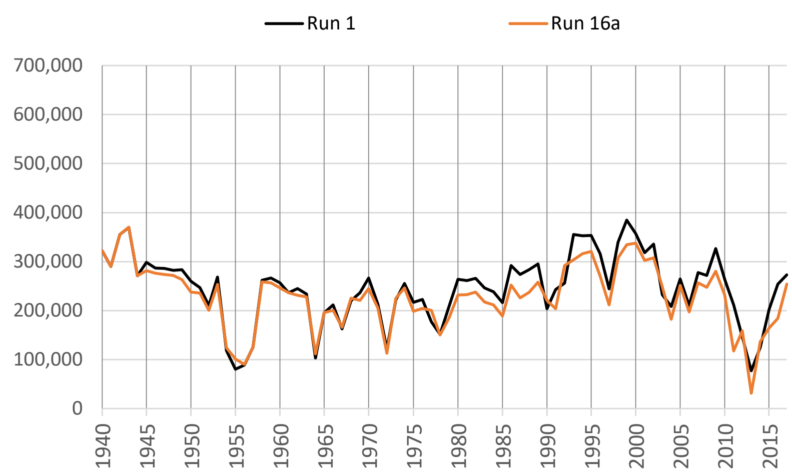
Run 16a v. Run 1

ILRG Model

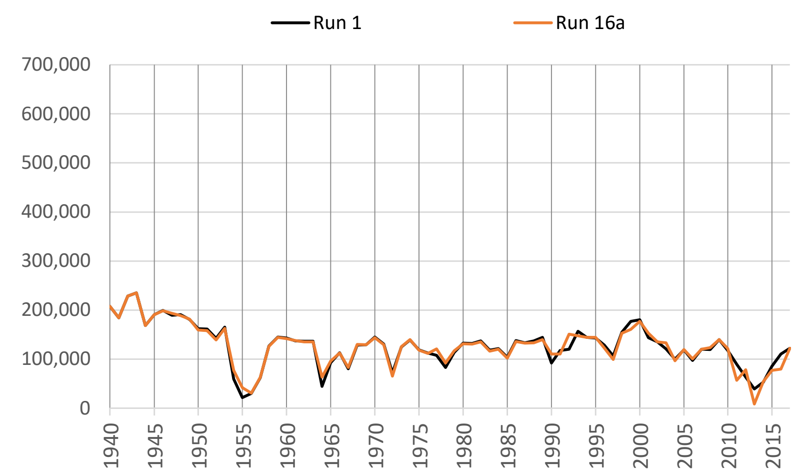
1940 - 2017 (acre-feet)

EPCWID Total

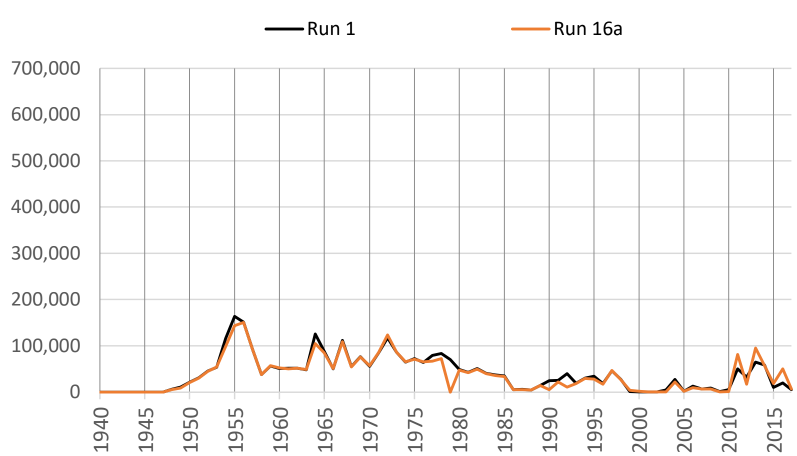
Net River Headgate Diversions



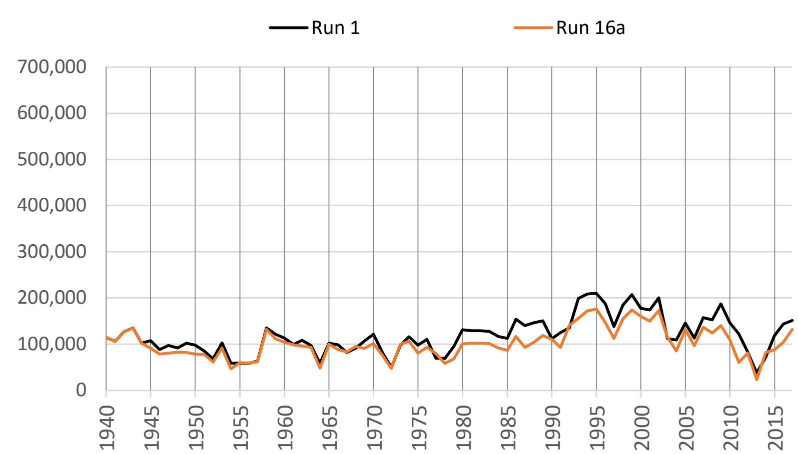
Farm Headgate Deliveries



Pumping



RHG Diversions - FHG Deliveries

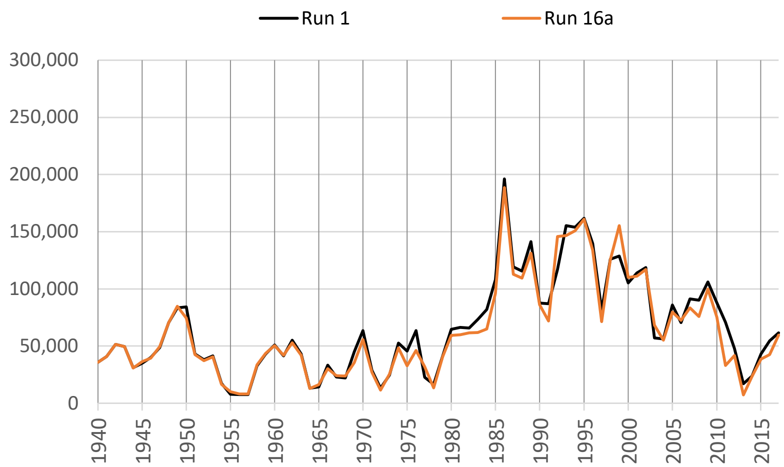


Note: EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

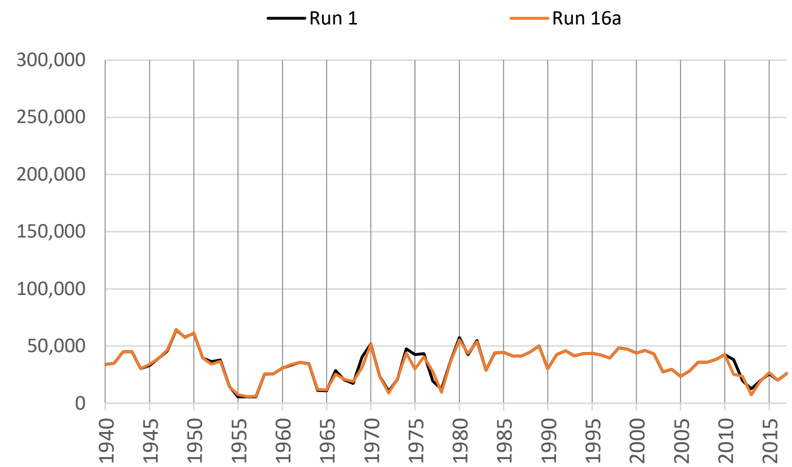
Run 16a - Conj Use 1a: Hist All Acres D1/D2 (1978 M&I)
Irrigation Season Summary of Irrigation Operations
Run 16a v. Run 1
ILRG Model
1940 - 2017 (acre-feet)

HCCRD Total

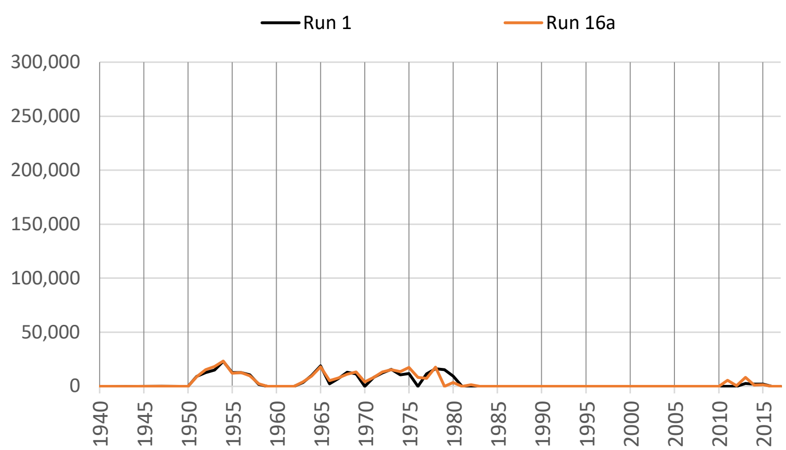
Net River Headgate Diversions



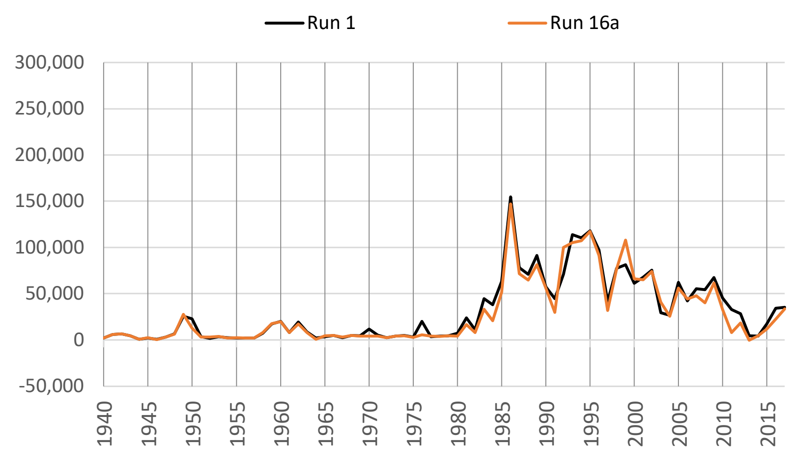
Farm Headgate Deliveries



Pumping



RHG Diversions - FHG Deliveries



Note: HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run 16a - Conj Use 1a: Hist All Acres D1/D2 (1978 M&I)

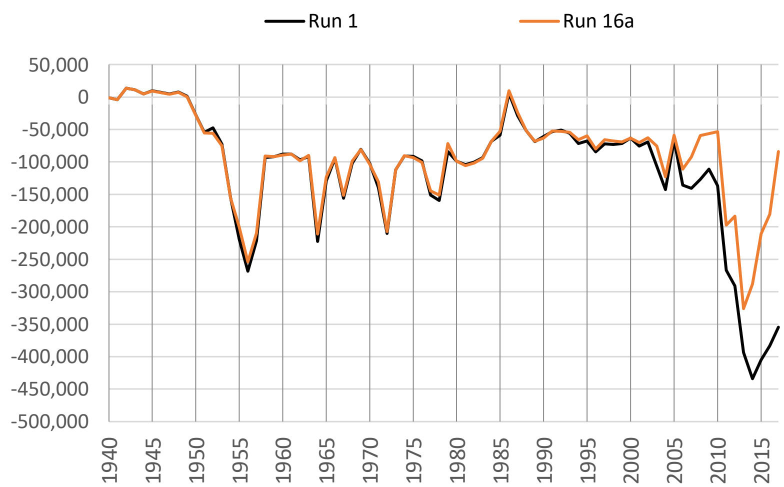
Cumulative Change in Ground Water Storage

Run 16a v. Run 1

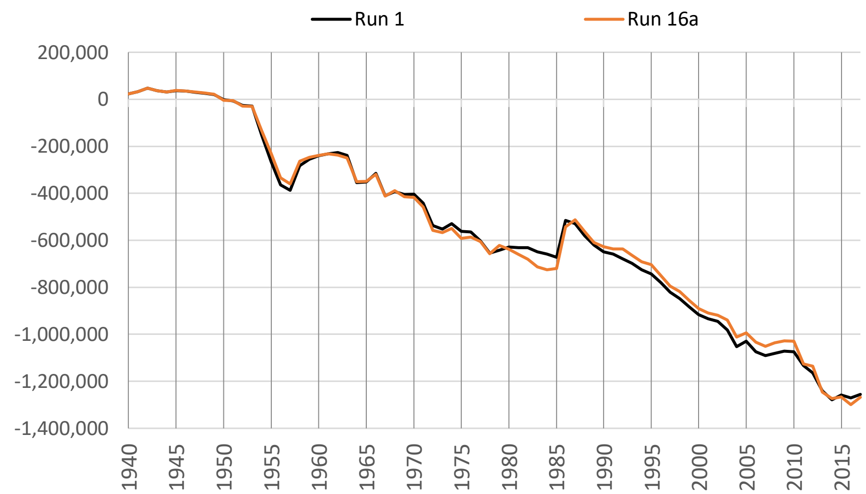
ILRG Model

1940 - 2017 (acre-feet)

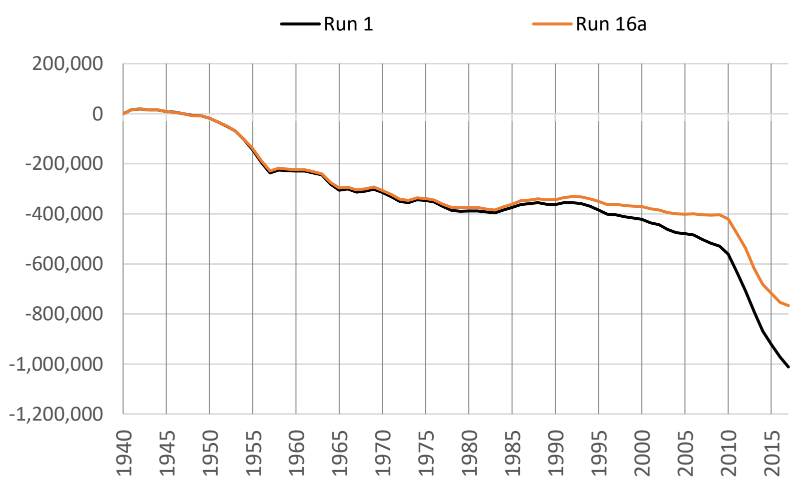
Rincon-Mesilla Alluvial Aquifer



Hueco Alluvial Aquifer



Rincon-Mesilla Non-Alluvial Aquifer



Hueco Non-Alluvial Aquifer

Comparison of ILRG Model Runs
Run 17 v. Run 1

Model Run Specifications

Model Version: LRG_v116

Name: **Run 17 - Conj Use 2: Hist Proj Acres (Hist M&I)**

Run ID: LRG_v116_Operational_Run17
Date: 8/28/2020

Name: **Run 1 - Historical Base Run (All Pumping On)**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

	Pumping and Returns	Run 17	Run 1
(1)	Irrigation Pumping	Conj	On
(2)	Irrigated Area	Project	Hist
	Non-Irrigation Pumping	On	On
	Non-Irrigation Pumping Returns	On	On
	Las Cruces Jornada Pumping Returns	Off	On

	Project Allocation Rules	Run 17	Run 1
	1950-2005	D1/D2	D1/D2
	2006-2007	D1/D2	D3
	2008-2017	D1/D2	D3 + CO

	EPCWID Operations	Run 17	Run 1
	Charge EPCWID for Use of WWTP Returns	On	Off
	ACE and Haskell Credits for EPCWID	Off	On
(3)	Increased EPCWID Use of Fabens Drain Flows	On	Off
	Charge EPCWID for Fabens Drain Flow Use	On	Off

Notes:
(1) Conjunctive use pumping on historical Project acres; no pumping on NM GW only acres.
(2) Project acres set to historical. New Mexico groundwater only acres set to 0.
(3) Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 AF/month.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Run ID: LRG_v116_Operational_Run17a
Date: 8/31/2020

Name: **Run 1 - Historical Base Run (All Pumping On)**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

	Pumping and Returns	Run 17a	Run 1
(1)	Irrigation Pumping	Conj	On
(2)	Irrigated Area	Project	Hist
(3)	Non-Irrigation Pumping	Pre-Comp	On
	Non-Irrigation Pumping Returns	Pre-Comp	On
	Las Cruces Jornada Pumping Returns	Off	On

Project Allocation Rules		
1950-2005	D1/D2	D1/D2
2006-2007	D1/D2	D3
2008-2017	D1/D2	D3 + CO

	EPCWID Operations		
	Charge EPCWID for Use of WWTP Returns	On	Off
	ACE and Haskell Credits for EPCWID	Off	On
(4)	Increased EPCWID Use of Fabens Drain Flows	On	Off
	Charge EPCWID for Fabens Drain Flow Use	On	Off

Notes:
(1) Conjunctive use pumping on historical Project acres; no pumping on NM GW only acres.
(2) Project acres set to historical. New Mexico groundwater only acres set to 0.
(3) Limit M&I pumping to pre-compact levels. Reduce corresponding return flows.
(4) Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 AF/month.

Notes:

EBID Net RHG Diversions are sum of Arrey, Leasburg, Eastside, and Westside minus EPV carriage, increased spill diversions, and flows to TX Mesilla (x 1.15 or 1.2 for losses).

EPCWID Net RHG Diversions are sum of Franklin Canal gage, Riverside Canal gage, Rogers WTP, R/U WTP, TX Mesilla minus Ascarate Wasteway and increased spill diversions.

HCCRD Net RHG diversions are sum of Hudspeth Feeder Canal, Tornillo Drain, and Tornillo Canal at Alamo Alto.

Model Run Specifications

Model Version: LRG_v116

Name: **Run 18 - Conj Use 3: Auth Proj Acres (Pre-Comp M&I)**

Run ID: LRG_v116_Operational_Run18
Date: 8/31/2020

Name: **Run 1 - Historical Base Run (All Pumping On)**

Run ID: LRG_v116_Operational_Run1
Date: 8/23/2020

Selected Model Inputs

	Pumping and Returns	**Run 18**	**Run 1**
(1)	Irrigation Pumping	Conj	On
(2)	Irrigated Area	Authorized	Hist
(3)	Non-Irrigation Pumping	Pre-Comp	On
	Non-Irrigation Pumping Returns	Pre-Comp	On
	Las Cruces Jornada Pumping Returns	Off	On
	Project Allocation Rules		
	1950-2005	D1/D2	D1/D2
	2006-2007	D1/D2	D3
	2008-2017	D1/D2	D3 + CO
	EPCWID Operations		
	Charge EPCWID for Use of WWTP Returns	On	Off
	ACE and Haskell Credits for EPCWID	Off	On
(4)	Increased EPCWID Use of Fabens Drain Flows	On	Off
	Charge EPCWID for Fabens Drain Flow Use	On	Off

Notes:
(1) Conjunctive use pumping on historical Project acres; no pumping on NM GW only acres.
(2) Acres set to authorized Project acres every year. HCCRD set to max historical acres.
(3) Limit M&I pumping to pre-compact levels. Reduce corresponding return flows.
(4) Starting in July 1945, use 70% of simulated Fabens drain flow up to 6,000 AF/month.

Table of Contents

List of Figures

List of Important People

Name	Role
Prof. Frank Adams	National Resources Committee, Co-Head of Rio Grande Joint Investigation
Prof. Harlan Barrows	National Resources Committee, Co-Head of Rio Grande Joint Investigation
John Bliss	New Mexico Engineering Advisor
Major Richard Burgess	Texas legal adviser
Delph Carpenter	Colorado Rio Grande Compact Commissioner, 1920s
Ralph Carr	Colorado legal advisor
Frank Clayton	Texas Rio Grande Compact Commissioner, 1930s
George Corlett	Colorado legal adviser
E.B. Debler	Reclamation Chief Engineer, 1930s, also United States engineering advisor during Compact negotiations
L.R. Fiock	Rio Grande Project Superintendent, 1920s-1940s
S.O. Harper	Reclamation Asst. and later, Chief Engineer 1930s, and United States representative/chair, Rio Grande Compact Commission Chair
Roland Harwell	Manager of EPCWID, 1920s, 1930s
M.C. Hinderlider	Colorado State Engineer, Rio Grande Compact Commissioner, 1930s
L.M. Lawson	Rio Grande Project Superintendent,1920s; International Boundary Water Commission, 1930s
Thomas McClure	New Mexico State Engineer, RG Compact Commissioner, 1920s-1930s
T.H. McGregor	Texas State Engineer, Rio Grande Compact Commissioner, 1920s-early 1930s
Elwood Mead	Commissioner, Reclamation Service/Bureau of Reclamation, 1924-1936
Ralph I. Meeker	Colorado irrigation engineer, 19teens and 1920s
John C. Page	Commissioner, Reclamation Service/Bureau of Reclamation, 1936-1943
Harlow M. Stafford	Engineer in Charge, Rio Grande Joint Investigation
Royce J. Tipton	Colorado engineering adviser
F.E. Weymouth	Reclamation Chief Engineer, 1920s
Francis Wilson	Texas Rio Grande Compact Commissioner, 1920s

Statement of Qualifications

Author's Background and Scope of Work

My name is Jennifer Stevens. I earned a Ph.D. in History at University of California, Davis in 2008. Prior to that, I earned a Master of Arts Degree in History in 1995, and Bachelor of Arts Degrees in Political Science and History in 1993, all at University of California, Santa Barbara. I have been conducting historical research in the public sector for litigation and other purposes since 1995. I am a Professor of Practice and an Assistant Clinical Professor in the School of Public Service at Boise State University, where I teach classes in Urban and Environmental History.

Trial and Deposition Experience

In the past five years, I have provided deposition and trial testimony as follows:

Deposition Testimony

2018: United States v. Pioneer Natural Resources Company et al, Civil Action 1:17-CV-00168-WJM-NYW

2018: Billings County, et.al v. United States of America 1-12-CV-00102-DLG-CSM

2016: Cyprus Amax Minerals Company v. TCI Pacific Communications and CBS Operations, Inc. (11-CV-252-JED-PJC, Federal District Court, N.D. Okla)

2015: Snake River Basin Adjudication Subcase Nos. 63-33732, 63-33733, and 63-33734

2014: Shoshone-Bannock Tribes Land Use Department and Fort Hall Business Council vs. FMC Corporation (C-06-0069, C-07-0017, C-07-0035)

Trial Testimony

March 2018: David Stanley v. Board of County Commissioners of Mora County, et. al. (D-809-CV-2011-00252, Taos District Court, State of New Mexico).

February 2018: Cyprus Amax Minerals Company v. TCI Pacific Communications and CBS Operations, Inc. (11-CV-252-JED-PJC, Federal District Court, N.D. Okla)

April 2014: Shoshone-Bannock Tribes Land User Department and Fort Hall Business Council vs. FMC Corporation (C-06-0069, C-07-0017, C-07-0035)

History of Western Rivers Experience

I have investigated the history of several western rivers on behalf of clients engaged in matters related to water development and management in the West since the 1990s. Some of those rivers are listed here:

- Boise River (Idaho);
- Big Wood River (Idaho);
- Columbia River (Washington/Oregon);

- Deschutes River (Oregon);
- Duwamish River (Washington);
- Gila River (Arizona)
- Kern River (California);
- Little Missouri River (North Dakota);
- Little Salmon River (Idaho);
- Missouri River (North Dakota);
- North Platte River (Nebraska);
- Payette River (Idaho);
- Pecos River (New Mexico);
- Salmon River (Idaho);
- Salt River (Arizona);
- Snake River (Idaho);
- Verde River (Arizona).

I have worked on behalf of irrigation districts as well as state agencies. Additional details about my educational and professional background can be found in Appendix B at the back of this report.

Methodology and Materials Consulted

For the current matter, I was contacted by counsel for the New Mexico Office of the Attorney General in 2013 to investigate the history of New Mexico and Texas's use of the Rio Grande waters, especially leading up to and during negotiations for the Rio Grande Compact of 1938. Broadly speaking, I was tasked with exploring the following overarching questions:

- What were the Compact Commissioners' understandings of the intent of the 1938 Compact and how it would impact the management of Project water within the states?
- How did officials manage groundwater, and what connections did they make between groundwater use and Project surface water?
- What was the intent regarding the water that was allowed to be delivered to the Hudspeth County Conservation and Reclamation District No. 1?

To conduct this study, I employed the typical and accepted historical research methodology. I began by reviewing materials provided to me by counsel, all of which can be found at the New Mexico Office of the State Engineer (NM OSE) Library. I then traveled to and/or reviewed primary sources from a variety of repositories:

- El Paso Times and El Paso Herald, 1917-1923 (newspapers.com);
- Records of the Bureau of Reclamation, R.G. 115 (U.S. National Archives, Denver);

- Elephant Butte Irrigation District Records, 1906-1969, MS235 (New Mexico State University Library);
- Raymond A. Hill Papers, 1890-1945 (University of Texas, Austin);
- New Mexico State Engineer Records, 1888-[ongoing] (New Mexico State Records and Archives);
- Governor Clyde K. Tingley Papers (New Mexico State Records Center and Archives);
- Governor John E. Miles Papers (New Mexico State Records Center and Archives);
- Miscellaneous papers boxes (New Mexico Interstate Stream Commission, Basement);
- Rio Grande Compact Commission Records, 1924-1942 (University of Texas, Austin);
- Rio Grande Compact Commission Records, 1939-1968, MS406 (University of Texas, El Paso);
- Frank Adams Papers (University of California, Riverside);
- Records of the National Resources Planning Board, Region VII, R.G. 187 (U.S. National Archives, Denver);
- Records of the Geological Survey, R. G. 57 (U.S. National Archives, II);
- Records of Texas Governor James Allred, 193101939 (Texas State Library and Archives Commission);
- Records of the Texas Water Commission, 1913-1986 (Texas State Library and Archives Commission);
- Records of the Texas Reclamation Engineer, Historical Files, ca. 1908-1960, Acc. 1982/006 (Texas State Library and Archives Commission);
- Records of Boundary and Claims Commissions and Arbitrations, 1716-1994, R.G. 76 (U.S. National Archives, II);
- International Boundary & Water Commission, R.G. 76 (U.S. National Archives, Fort Worth);
- Records of the National Resources Planning Board, R.G. 187 (U.S. National Archives, II);
- Records of the Soil Commission Service, R.G. 114 (U.S. National Archives, II);
- Records of the Office of the Chief of Engineers, R. G. 77 (U.S. National Archives, Denver);
- General Records of the Department of State, R. G. 59 (U.S. National Archives, II);
- El Paso (Texas) Irrigation Study Records, 1994 (University of Texas, Austin);
- Richard Fenner Burges Papers, 1897-1940 (University of Texas, Austin);
- Texas Water Commission Minutes, 1991/041, 1992/043 (Texas State Library and Archives Commission);
- Records of the Texas Natural Resource Conservation Commission, Water Rights Application Files (Texas State Library and Archives Commission);

After gathering relevant documents, I reviewed and analyzed them, after which I wrote the following report. My primary conclusions are listed below in “Expert Opinions.”

All publications as well as all matters in which I have offered testimony over the previous four years can be found in Appendix B.

Statement of Compensation

I am compensated at a rate of $150 per hour for the work performed in this matter. My compensation is not dependent on the substance of my opinions or the outcome of this litigation.

Expert Opinions

1. The use of the waters of the Rio Grande's Upper Basin evolved over time, often resulting in significant interstate and international tensions. Operations on the river were in near-constant flux after the federal government began engineering and controlling its flows. The Bureau of Reclamation and other federal agencies made frequent changes to Rio Grande Project infrastructure aimed at attempting to make the system operate more efficiently and/or solving international issues with Mexico. The 1938 Rio Grande Compact built flexibility into its administration to accommodate such ongoing and anticipated future changes.

2. The success of the Rio Grande Project depends upon the administration of the water to the lands within the project boundary as a single unit, with an equal allocation of water to each Project acre. In fact, the compromise at the 1904 Irrigation Congress in El Paso depended upon this conceptual administration and permitted the parties to finally agree to the Elephant Butte Dam over the International Dam at El Paso. This concept of a unified Project was recognized by the framers of the 1938 Rio Grande Compact.

3. Lands in the Hudspeth County Conservation and Reclamation District have never been included within the Rio Grande Project boundaries and, despite several unsuccessful efforts to join the Project or to secure a reliable source of water, have never been entitled to receive water other than the unavoidable waste from the Project. Reclamation consistently and repeatedly informed Hudspeth that waste water delivered to its boundary at the lower end of the Project would always be unreliable and secondary to uses on Project lands. Reclamation officials recognized the obligation to operate the Project as efficiently as possible, and chose to attempt to improve Project efficiencies over time, even knowing that such increases in efficiencies could lead to reductions in "unavoidable waste" at the end of the Project, which would have the effect of reducing water available to Hudspeth users. Therefore, Hudspeth's water supply was always in jeopardy, even after the 1938 Compact was signed. Any concept that the framers of the 1938 Rio Grande Compact intended to maintain a supply of water for Hudspeth users at the levels they were receiving at the time the Compact was negotiated and signed is contrary to the entire body of historical evidence.

4. During the negotiations leading to the 1938 Rio Grande Compact, Texas used the issue of water quality to demand and receive a higher "normal release" of water from Elephant Butte Reservoir than would otherwise have been justified based on the needs of irrigable Project acreage alone, but not to provide any additional supply of water for lands below the Project.

5. The United States' Rio Grande Project water filings with the New Mexico Territorial Engineer in 1906 and 1908 did not include, nor were they intended to include, the Upper Rio Grande Basin's groundwater. The scientific understanding of connections between groundwater and surface water was too nascent in the first decades of the 20th century for Reclamation to have intended such an overreach, and the historical record provides no support for a contradictory conclusion.

6. Scientific understanding of the relationship between surface and groundwater supplies in the Upper Rio Grande Basin was still in its infancy at the time of the 1938 Rio Grande Compact negotiations, and the Rio Grande Joint Investigation gave scant attention to the issue of groundwater, particularly in the area below Elephant Butte Reservoir, partly at the insistence of Texas. Simply put, the Compact

framers did not evince an intent to preclude future groundwater development in the basin. All parties understood that the 1938 Rio Grande Compact was not intended to freeze development in the Upper Rio Grande Basin, as had been the intent of the 1929 temporary Compact, but instead understood that it was designed to provide a realistic path forward for future additional development throughout the basin, consistent with the rights of each compacting state.

Introduction

The Rio Grande rises in Colorado's San Juan Mountains, and flows 1900 miles through Colorado, New Mexico, Texas, and Mexico to the Gulf of Mexico. The Upper Rio Grande Basin stretches from the river's headwaters south through many valleys of rich farmland as well as major American and Mexican cities that have grown in population over the past 150 years, ending at the narrows below Fort Quitman, the natural dividing point of the river from the Lower Rio Grande Basin. Policy makers have always deemed the location of this former Army fort (abandoned in the 1880s) to be the natural hydrological dividing point of the river, since below this point, tributaries with headwaters on the Mexican side of the river contribute their runoff to the Rio Grande, constituting the majority of its volume thereafter. Along the river's route from Colorado to Fort Quitman, both farmers and cities divert and return the Rio Grande's water over and over, using it to water crops, provide drinking water, and power factories. The major agricultural valleys in downstream order are the San Luis Valley in Colorado, the Middle Rio Grande, the Palomas, Rincon, and Mesilla Valleys in New Mexico, and the El Paso and Hudspeth Valleys in Texas. Likewise, the major cities along the river in downstream order include Albuquerque and Las Cruces in New Mexico, El Paso in Texas and Juarez in Mexico, the latter two of which are situated across the Rio Grande from one another. Fort Bliss, a United States Army base, is located in metropolitan El Paso, northeast of the city.

In prehistoric times, the river's water was ample to provide for the needs of the small communities situated along its banks. The regular spring floods scoured the valley floor and the silt-laden water brought nutrients to the surrounding lands, making fertile soil for agriculture. But as white American settlement encroached in the mid-19th century, increasing demands on the limited resource led to battles over the right to use it. The battles were fought farmer to farmer, county to county, state to state, and even country to country.

As a result, the Rio Grande today is highly engineered and tightly regulated, the resource having been legally relegated to strict use limits after many courtroom fights. Water is stored behind several dams, including the Rio Grande Project's Elephant Butte Dam, the system's largest, from which water is released during the dry summer months and delivered to canals and laterals that serve arid lands which claim long-standing water rights. Because the Bureau of Reclamation's Rio Grande Project controls such a large volume of water in a long stretch of the river between New Mexico and Texas, operation of the river system as a unit has been a fundamental tenet of the river's management. With varying degrees of scientific understanding, Project managers have historically recognized that many factors can affect delivery of water along the entire river, whether downstream or upstream, and that any change to a single factor could result in wholesale changes to the Rio Grande's operations in any given year. From the earliest years of river management at the turn of the 20th century all the way up to the present, comprehension of the effects related to illegal excess diversions, volume of irrigated acreage, duty of water, and groundwater pumping have gradually improved and become more precise, leading to an evolution of management decisions over the decades.

This report will provide the history of water use on the Rio Grande as well as the interlocking work of various federal entities from the 1890s forward. Specifically, it will detail the history of the years leading up to and including the formation of the Rio Grande Project ("Project"), examining the role of international diplomacy in the river's management as well as the domestic policy goals that were incorporated into the Project's development. It will also examine the role that the United States has played in protecting domestic users from infringements on the resource by Mexican water users. Finally, the report will investigate the role of the Project in the 1938 Rio Grande Compact ("Compact") negotiations, the parties' goals during the agreement's lengthy negotiation process, and the Compact's implementation in the years following ratification.

Chapter 1: Setting the Stage: 1890s to 1920s

Origins of Conflict

The years leading up to the authorization of the Rio Grande Project in 1905 were rife with tension and dissent among river users. Along the river's entire length, disputes had arisen about excess depletions. Up near the river's headwaters in southern Colorado, a wave of settlers had descended upon the San Luis Valley in the late 1880s and early 1890s, settling on and proving up lands for new farmsteads. Meanwhile, hundreds of miles away, Mexico's downstream uses were also expanding, and that country complained that Colorado settlers' actions were harming their water rights.

Other downstream users located in New Mexico and Texas also blamed Colorado for water shortages, and it was easy to see how they drew that conclusion. The federal government had granted homestead patents to hundreds of thousands of acres in Colorado in the late 19th century. By 1891, more than 2,000 artesian wells had been dug to water lands in the San Luis Valley,[1] and by 1892, 925 irrigation ditches were diverting enough water from the surface waters of the Rio Grande to irrigate 400,000 acres in Colorado alone.[2] With those numbers, it was logical to conclude that Colorado's rapid increase in depletions were the cause of shortages for downstream users.

Several responses to the shortages emerged from the downstream water users. First, citizens in New Mexico and Texas formed the Rio Grande Dam & Irrigation Company in 1893 for the express purpose of building a storage dam at Elephant Butte in New Mexico's Palomas Valley, and obtained a right of way from the Secretary of the Interior to construct the structure over public lands.[3] Second, Mexico engaged in diplomatic negotiations with the U.S. State Department, registering official complaints about the United States' taking of Mexican water that belonged to that country by prior right.[4] Third, under the authority of the 1889-established International Boundary Commission, the U.S. Army Corps of Engineers and engineers from Mexico initiated an investigation of water use along the Rio Grande in 1896 to provide data to the U.S. government with which to make informed decisions about the river's management. The purpose of the 1896 study was two-fold. First, the United States needed to determine whether its citizens had in fact taken Mexico's water which they claimed belonged to them by "ancient right of prior appropriation."[5] Second, the United States wanted to assess whether there was adequate water in the river to construct a dam for storage at El Paso – in addition to the private dam planned upstream at Elephant Butte – which could assist the United States in compensating Mexico some of its water.[6]

The findings of the 1896 study were devastating to Colorado. Civil Engineer W.W. Follett, who worked for the International Boundary Commission, found that water use in Colorado had increased by 200% since 1879 and concluded that expanding diversions there led to downstream flows at El Paso that were 1,000 cubic feet per second (cfs) lower than they would have been without Colorado's increasing depletions.[7] The study also found

that there was not enough water in the river to support construction of both the private dam at Elephant Butte as well as a government dam at El Paso; "one of these projects, in the opinion of the [International Boundary] commission must give way to the other, or at least, if both are built, that at Elephant Butte must in some way be restrained from using water already appropriated by the citizens of the El Paso Valley, both Mexicans and Americans."[8]

The United States government responded to the study results with swift and firm actions, some of which were recommended by Mexico. First, on December 5, 1896, the U.S. Secretary of the Interior directed its sub-agency, the General Land Office, to suspend all right-of-way applications for irrigation through public lands in the Rio Grande Basin in Colorado and New Mexico.[9] This action became known as "the embargo," and the restriction (with some modifications) remained in place until the 1920s. Second, following a series of discussions and actions, the U.S. Attorney General officially opined that the Rio Grande was a navigable river. His ruling had the effect of suggesting that right of way granted to the Rio Grande Dam and Irrigation Company was invalid, since the Secretary of the Interior had not possessed the legal power to grant it. Instead, the Secretary of War was the only official empowered to grant such a right over navigable waters.[10] The United States had determined that solving the diplomatic water dispute with Mexico would require the construction of a government-sponsored project that could deliver water annually to Mexico. Since the company was unwilling to give up the right-of-way voluntarily, and Follett's report had clearly stated that there was not enough water in the river for two dams, the United States would have to do everything in its power to stop the private dam from being built. The Attorney General's opinion provided the basis, then, for the United States to file a lawsuit against the Rio Grande Irrigation & Land Company (successor to Rio Grande Dam & Irrigation Company) in 1897 to enjoin it from constructing the dam at Elephant Butte.[11]

Choosing a Site: Locating the Rio Grande Project

The dispute regarding the construction of a dam on the stretch of the Rio Grande between the New Mexico Territory/Texas state line sorted people into two camps according to which site they preferred. Those who supported the privately constructed dam at Elephant Butte were mostly New Mexicans, including water users in the Mesilla Valley whose irrigation through community ditches and artesian wells stretched back hundreds of years.[12] These farmers were suffering through the first years of what proved to be a very long period of lower-than-average precipitation in the basin lasting from the early 1890s through 1904; in fact, at least one hydrographer from the U.S. Geological Survey (USGS) who studied irrigation in the Mesilla Valley, F.C. Barker, believed in contrast to Follett that the ongoing drought was more responsible for downstream shortages than Colorado's increased diversions upstream, and that the United States perhaps should not base the policy decision on a dam on the current drought and the dispute with Mexico.[13] New Mexico's official stance also favored the Elephant Butte project. The New Mexico Territorial Governor called the United States' assertions of the Rio Grande's navigability "preposterous,"[14] and accused downstream users of orchestrating the lawsuit

because they feared monopolization of the water by New Mexican farmers.[15] However, it was not true that everyone downstream in Texas supported the alternative dam, as evidenced by the El Paso Chamber of Commerce (which later established the El Paso Valley Water Users Association)[16] resolving to support the Elephant Butte Dam in 1900.[17]

Meanwhile, most citizens who depended on river water downstream of New Mexico, including farmers in the El Paso and Juarez areas, were concerned that construction of a private dam upstream would further constrain water use in Texas and Mexico, as opposed to helping their situation. Therefore, in support of a dam further downstream and closer to them, they took steps to make possible what they called the International Dam at El Paso. This was the position the United States government supported, as well, much to the frustration of upstream users. Nathan Boyd, leader of the Rio Grande Dam and Irrigation Company which had proposed the private dam at Elephant Butte, wrote letters to several high-ranking officials in the United States government, including the Secretary of State and the Attorney General, to argue for the value of his plan, and disagree with the attorney general's finding regarding the ability to navigate the river above Fort Quitman. He accused the federal government of sacrificing the irrigation rights of Colorado and New Mexico in the interest of an international dam "scheme."[18] However, even with the United States on the losing side of the early decisions in the legal battles with Boyd's company in both New Mexico Supreme Court and the United States Supreme Court,[19] diplomats in the State Department faced such pressure from the Mexican government that its officials continued to push for the dam they believed could permanently solve the diplomatic impasse, despite the support enjoyed by Boyd's plan both in New Mexico and some parts of Texas.[20]

Developing the Rio Grande Project

Mexico, while somewhat mollified by the 1895 embargo on upstream uses, nevertheless continued to pressure the United States to guarantee Mexico's prior water rights into the 1900s and believed that construction of a storage dam at El Paso would serve that purpose. During the several years it took for the legal dispute between the United States and Nathan Boyd's company to wind its way through the courts, Congress passed the Newlands (or Reclamation) Act in 1902.[21] This law created the United States Reclamation Service, a federal agency empowered to identify, fund, and construct irrigation systems across the arid western states. Because of the international dispute over the Rio Grande and the increasingly tense regional situation, the new Reclamation Service proposed the Rio Grande Project – comprised of a single large storage site on the Rio Grande and related irrigation infrastructure – as one of its first projects.

In 1903, two figures who were intimately familiar with the river's inner workings exchanged confidential letters. USGS Chief Engineer F.H. Newell, who had conducted the earlier study of irrigation in the Mesilla Valley and favored the Elephant Butte site, wrote to W.W. Follett, who had conducted the 1896 investigation for the International Boundary Commission and favored the El Paso dam site. Newell, who was investigating the best location for a Reclamation-sponsored dam, wanted Follett's opinion as to which location on the river was truly best for water storage. Newell acknowledged that Follett was officially "committed to the project of water storage at El Paso," but

wondered if Follett might tell him confidentially whether he believed "this is the best use of the water of the river."[22] Follett responded that from an engineering perspective, a different dam entirely, located in the lower Espanola Valley (near Santa Fe) might be the most ideal. But in his mind, there was far more than engineering at stake: "our National honor in our treatment of a weaker power" was the more significant issue. Follett remained committed to the El Paso dam because it was, in his mind, the best way to provide absolute justice for Mexico's claim.[23] Following Reclamation surveys conducted in 1903-1904 during which agency engineers took borings of the bedrock at Elephant Butte to determine its safety and stability among other testing, Reclamation determined in 1904 that the Elephant Butte site was superior to the El Paso site.[24] Even Boundary Commissioner Follett – who had long supported the El Paso site – came to support the Elephant Butte Dam site in later years, since it could store more water while also serving to provide a diplomatic solution with Mexico.

Events over the next few years led to resolution of the two key outstanding issues on the river: the diplomatic impasse with Mexico and the equitable delivery of water to American farmers in both New Mexico and the El Paso valley as well as Mexican farmers. Reclamation engineer Benjamin M. Hall, speaking at a meeting of the (non-binding but highly influential) National Irrigation Congress in 1904, compared the two dam proposals succinctly. At the El Paso meeting, Hall explained that the International Boundary Commission's proposal for a dam at El Paso had been made at a time when: 1) the Elephant Butte site was believed to be unavailable due to the right of way previously granted to the Rio Grande Dam & Irrigation Company to build a private dam there, and, 2) before the Newlands Act had become law. The El Paso site posed problems, because while it solved the delivery of water to Mexico to assure that country's prior rights, it would flood 40,000 acres of productive farmland in the Mesilla Valley of New Mexico. Hall stated that a government-sponsored dam at the Elephant Butte site – designed to be taller and with a much larger capacity to store water than the private proposal – would better serve all needs downstream in Texas and Mexico as well as lands in New Mexico without flooding fertile ground.[25] He also believed that a federal dam at the Elephant Butte site would resolve the water right conflicts between farmers in Mesilla Valley and those in the El Paso area.[26] Hall believed Elephant Butte was a better site, and the compromise that came out of the 1904 meeting paved the way for its construction. Reclamation counted on the Elephant Butte site becoming available after the litigation ceased, and proceeded accordingly.

One small problem was that delivering water to the lands in El Paso through infrastructure built with federal Reclamation money would require a change to the 1902 Reclamation law, which had not included Texas in its original jurisdiction. With the support of the House Committee on Foreign Affairs whose members recognized the value of the change to the United States/Mexico relations,[27] Congress effectively made that change in February 1905 when it approved the construction of a dam in the New Mexico Territory near Engle (Elephant Butte), extending the Reclamation Act to portions of Texas that bordered the Rio Grande and laying the foundation for the project to move forward.[28]

28 "An Act Relating to the Construction of a Dam and Reservoir on the Rio Grande, in New Mexico, for the Impounding of the Flood Waters of Said River for Purposes of Irrigation," Pub. L. No. 58–104, § 798, 33 Stat. 814 (1905); Congress passed an additional law in 1906 that

In anticipation of the Project's construction, water users in New Mexico and Texas formed Reclamation law-compliant associations to organize and administer both water deliveries and repayment obligations. In the north, landowners formed the Elephant Butte Water Users Association to represent farmers in the valleys of New Mexico, while downstream landowners in the El Paso Valley created the El Paso Water Users Association. Reclamation law required formation of these associations with which the federal government then contracted to ensure repayment for the infrastructure it financed.[29] These later became the Elephant Butte Irrigation District (EBID) and the El Paso County Water Improvement District No. 1 (EPCWID) respectively in 1918, according to New Mexico and Texas state laws.[30]

The Territorial Legislature of New Mexico also made preparations for development of the Rio Grande by creating the office of the Territorial Irrigation Engineer in 1905 through the adoption of an irrigation code that recognized the doctrine of prior appropriation.[31] To comply with the fundamental tenet that state law still applied to federal Reclamation projects, in January 1906 the United States submitted an application to the New Mexico Irrigation Engineer stating its intention to store 730,000 acre-feet of water annually in the Elephant Butte Reservoir.[32] The notice, provided by Reclamation Supervising Engineer Benjamin Hall who had engineered the 1904 Compromise at the Irrigation Congress, requested that "the waters above described be withheld from further appropriation and that the rights and interests of the United States in the premises be otherwise protected."[33]

While plans proceeded for Rio Grande Project construction by the U.S. Reclamation Service, the U.S. State Department continued its involvement in water supply, too, presiding over Mexican interests concerning the construction of the new dam.[34] Both Mexico and the United States perceived the Reclamation Dam as solving the international dispute over the river's supplies, and planned to deliver the storage water to Mexico as recompense. By April 1906, the United States had submitted a draft treaty to Mexico offering to provide enough water to irrigate 20,000-25,000 acres free of charge, in exchange for Mexico's agreement to waive its claims "in the international controversy or any other rights."[35] When Reclamation Service Director Frederick Newell testified in Congress in favor of the project and the proposed treaty, he explained that the water in the reservoir would be divided as such: enough water for 20,000-25,000 acres in Mexico; water for 110,000 acres in New Mexico, "and the balance below El Paso on the Texan side of the river."[36] On May 20, 1906 the United States signed a treaty which guaranteed Mexico 60,000 acre-feet of water annually – the compromise reached by the two countries and enough water to irrigate the Mexican acreage – delivered in the riverbed at the head of the Acequia Madre

Canal above the city of Juarez.[37] The treaty clearly laid out the water delivery schedule as well as plans for times of drought, and elucidated Mexico's waiver of any claim to the river's water between the head of the Acequia Madre downstream to Fort Quitman.[38]

By 1906, then, the system that became known as the Rio Grande Project, including the dam planned at Elephant Butte and a regulated system of water delivery, solved more than a single problem. It stored flood waters and spring runoff for use during the dry growing season, thereby regulating the river's irregular flow and supplying a more reliable water supply to American growers. But as significantly, the Project was a physical monument symbolizing the United States government's recognition of its role in solving an international dispute with Mexico. Mexico believed that farmers in the United States had stolen water that belonged to Mexican users through ancient rights, and this project provided those users with an assured annual supply.

The international importance of this project led to Congressional departure from the normal method of funding such Reclamation work. Under the typical structure, Reclamation Service projects were financed by the federal government advancing the funding to build the project infrastructure, and water users, organized into associations, paying back the cost of the dam and related infrastructure over time. However, in this case Congress decided that American farmers should not be burdened with the proportionate costs associated with treaty obligations to Mexico. Therefore, Congress appropriated non-Reclamation funds for a portion of Elephant Butte Dam's construction; out of an estimated $7.2 million cost, $1,000,000 of non-Reclamation money was slated to pay for Mexico's share of the dam's construction, at $4/acre, thereby relieving the Reclamation fund (and American farmers) from having to cover that portion of the cost.[39] This was done with the full approval of the Secretary of State, who agreed with Reclamation Director Frederick Newell (who had transferred from the USGS) that the United States should monetarily fulfill the country's treaty obligations with Mexico instead of burdening American farmers.[40] Finally, in March 1907, Congress authorized the dam's construction.[41] The State Department and the Department of Interior jointly instructed W.W. Follett – still working with the International Boundary Commission – to work with Reclamation engineers "in all matters pertaining to Reclamation work on the Rio Grande watershed."[42] A few years later, the U.S. Supreme Court resolved the litigation between the United States and the Rio Grande Dam and Irrigation Company in favor of the government,[43] and the Reclamation Service became free to construct a dam at the now unencumbered Elephant Butte site for its Rio Grande Project.[44]

Rio Grande Project Map. New Mexico Office of the State Engineer Library.pdf

Expansion of Project Boundaries

Between 1908 and 1924, the Reclamation Service built out the Rio Grande Project's infrastructure, including Elephant Butte Dam as well as diversion dams, canals, and laterals. Although the United States intended for the Project to provide a more reliable water supply for previously developed farms, the storage water behind Elephant Butte Dam would also permit the new development of irrigable acres that were not yet developed into farms. It was engineered to hold more than two million acre-feet of water, assuring an annual supply of between 750,000 and 800,000 acre-feet, enough to deliver treaty water to Mexico and to water 155,000 acres in the United States, with 110,000 of those in New Mexico and 45,000 in Texas.[45] To determine the water necessary for 155,000 acres, engineers assumed the following: duty of water at the farm – the amount of water necessary to deliver to the field to produce a successful crop – would be three acre-feet per acre, plus a 20 percent loss in the distribution system. The reservoir would also store 60,000 acre-feet to meet the United States' obligation to Mexico. Taken together, the requirement for release from the reservoir would be approximately 800,000 acre-feet. However, the system design also assumed that a portion of the water diverted in the upper reaches of the Project would return to the system for re-use further downstream: "losses in transit…will be partly offset by the return seepage in upper parts of the valley, which will be available for diversion lower down. It, therefore, appears that the available supply accords closely with the demand."[46] Nowhere did the documentation mention groundwater. Initial estimates had put the per-acre cost at $40/acre, but by the time the Secretary of the Interior finally authorized the dam in spring 1910, the total cost had risen to $9,665,000, or $56/acre for each of the 155,000 acres.[47]

Infrastructure construction began soon after the 1907 authorization and continued apace. In its final design stage, the Project consisted of the Elephant Butte Dam, four diversion dams, and all associated canal and lateral systems. Together the system would deliver water (in downstream order) to lands in the Rincon, Mesilla, and El Paso Valleys.[48] The Leasburg Unit in the Mesilla Valley, comprised of the Leasburg Diversion Dam and the Leasburg Canal, was the first project-related construction approved. Authorized and funded in 1907 and completed in 1908, it watered 25,000 acres in that valley by 1911. Reclamation constructed it first because it would offer the fastest relief to water users.[49] The other diversion dams and canals were not constructed in any geographical order, but instead in order of importance when funding was available. In New Mexico, construction began in 1914 on the Mesilla Diversion Dam, which diverted water into the East and West Side Canals in the Mesilla Valley, lying south of the city of Las Cruces, New Mexico.[50] Next was the Percha Dam, 25 miles south of Elephant Butte, constructed in 1918 to divert water to lands north of Las Cruces in the Arrey, Hatch, Garfield, and Rincon Districts in the Rincon Valley.[51] In the El Paso Valley in Texas, Reclamation purchased the pre-existing Franklin Canal from the private Franklin Irrigation Company in 1912 and enlarged it in ensuing years to carry 450

cfs to 45,000 acres in the El Paso Valley.[52] The Franklin was just upstream from the Acequia Madre canal, where Mexico took its treaty water on the Mexican side of the river. Elephant Butte Dam was finally completed in 1916 and began storing water that year, with a holding capacity of 2,639,000 acre-feet.

As was true on Reclamation projects across the West, the Rio Grande Project evolved over time. Although engineers surveyed the Elephant Butte Dam site and sketched the early outlines of the rest of the system, it was Congressional authorization (and regular appropriations) that provided the green light to comprehensively build the Project out, and the devil was in the details. Securing a reliable water supply for previously irrigated lands was an important piece of the Project's intent but extending irrigation to new lands for cultivation in the Rio Grande watershed, like in all Reclamation projects, constituted another significant Project aim. The Reclamation Service was an important tool in fulfilling the United States' policy and vision of settling the American West with small farmers. In 1915, as part of the Project's evolution, the Reclamation Service decided to survey lands that lay south of El Paso in the Tornillo Valley, downstream of both El Paso and Fabens, Texas, "in case it should be decided to incorporate this valley in the project later on." Prior to this survey, these extreme downstream lands had not "been investigated in connection with the Rio Grande project."[53] However, landowners there expressed their interest in becoming part of the Project and believed that if infrastructure could in fact be extended to reach them, their lands would benefit from the reliable irrigation offered by the Project. Whether the canals would be extended that far south, however, remained questionable as late as 1918. When the El Paso Water Users Association petitioned the Reclamation Service to extend the Project to include these Tornillo Valley properties, it was clear that the Tornillo landowners were willing and wanted to become a part of the Project, which meant forming and financially contributing to a water users association to pay back Reclamation construction costs.[54] Irrigable land totaling 7,600 acres in their area could obtain irrigation water if the main Tornillo Canal – already serving lands in upper districts – could be extended an additional 14 miles down the river.[55] To obtain Project water, landowners representing an existing 4,600 privately owned acres formed a new irrigation district called the El Paso County Conservation and Reclamation District No. 2 (EP2) in early 1919.[56] By the end of the year (a year in which 3,221 acres were already cropped in the district thanks to the area's preexisting community ditches),[57] the district was negotiating a service contract with the Reclamation Service and would officially become part of the Project.[58]

The Reclamation Service struggled internally over the next few years to determine how and whether to include other new lands in the Project. In 1919, Reclamation conducted topographic surveys in the newly incorporated Tornillo District but also in the unincorporated Fort Hancock area, located even further downstream in Hudspeth County.[59] However, Reclamation officials expressed concern over the water quality for lands so far south. They were committed to running an efficient Project and knew that the further downstream from Elephant Butte they delivered water to new lands, the poorer the water quality would be, due to the salts picked up by return flows. If the water was too salty, it was useless for crop development. Nevertheless, since the full project acreage was not yet developed needed for crops upstream, excess storage water was temporarily available in these lower lands to dilute the salty water and create a usable supply in the downstream areas.[60] Tornillo lands fell into that class, as did Fort Hancock lands, but Reclamation's internal dialogue in 1919 and 1920 demonstrated concern that such excess would not be available indefinitely. [Tornillo's and Fort Hancock – or "Hudspeth's" – water quality is discussed in detail in Chapter 5 below.]

The Reclamation Service had initially approached the irrigation of Tornillo Valley lands through the drafting of a contract under the Warren Act, a 1911 law enabling the agency to rent surplus water generated by its projects.[61] The agency's uncertainty with regard to future water supply for Tornillo's lands led first to a one-year Warren Act contract, offering rental water to EP2 landowners. But as the agency looked to the future, Reclamation officials saw the opportunity to create water use efficiencies, and asked EP2 landowners to consolidate their river headings into a single diversion in order to create a system that met the efficiency demands of the Project and the water quality demands of EP2 lands.[62] Simultaneously, the Reclamation Service had been internally discussing whether to bring the Tornillo District into the official fold of the Rio Grande Project. Bringing Tornillo lands into the official Project boundaries would provide the landowners with access to Reclamation project funding to make the infrastructure changes recommended for efficiency but would also ensure that the Reclamation Service would receive repayment for its investment. A draft contract was prepared but not initially shared with the district because Reclamation could not yet offer funds to execute on the recommended construction.[63]

Eventually, the Project included the Tornillo lands through a permanent contract signed in 1920 between Reclamation and EP2, incorporating these lands into the Project on par with the other Project lands and giving Tornillo District landowners the same rights and obligations as other Project participants.[64] Once fully developed,

the Tornillo District would be served by a single canal that took its water at a diversion near Fabens, Texas, several miles downstream from El Paso; 12 miles of a 150-cfs capacity main canal; 18 miles of lateral canals to cover 160-acre farms; a trunk line drain to empty at the lower end of the Project; and 17 miles of lateral drains.[65] By 1920, with the Tornillo District now boasting more than 4,000 acres in production, EPCWID and EP2 merged into a single organization, with the Tornillo District lands coming under the administration of EPCWID.[66] Officials probably hoped that improvements to delivery efficiencies (e.g. a single diversion instead of many) would help solve the water quality issue, as well, but salty water continued to be an issue for those landowners well into the future.

Although officially part of the Project now, Tornillo District lands were not immediately reachable by Project facilities, nor was the consolidation of the district lands into the Project simple. In the years leading up to 1923 when construction of the Tornillo Canal was completed,[67] lands in that and other districts diverted their stored water directly from the river through old community ditches that had predated the Project's construction.[68] As noted above, in order to properly deliver water of useable quality to Tornillo, it would be necessary for Reclamation to combine the diversions into a single canal heading. Nevertheless, annual Reclamation project reports included Tornillo District acreage as soon as they were officially a part of the Project, while specifically excluding acreage (and enumerating the exclusion) in other districts nearby, including Fort Hancock.[69]

Fort Hancock lands were excluded from reports because the Reclamation Service had briefly considered bringing these extreme downstream lands into the Project during this same era. However, when Reclamation offered Project status to water users in the Fort Hancock District these water users had reportedly "refused to bring the same within the limits of the Rio Grande Project."[70] Although the historical record is scant regarding the reasons for the Fort Hancock water users' refusal, the local papers also reported that although the initial plans for Project expansion had included these farmers, "this was given up."[71]

Despite Fort Hancock landowners' refusal to join the Rio Grande Project, irrigation was critical to their lands' development. Their refusal, however, had left them in a suboptimal position when it came to Project water delivery. Although Reclamation was committed generally to providing irrigation to as many acres as possible, Fort Hancock users' choice not to join the Project meant that they (and any other non-Project user) had no permanent or assured right to any of the Project's water. For example, although Reclamation's Board of Engineers met in 1919 and established the Rio Grande Project limits at 150,000 acres, a new landowner who had purchased 10,000 acres in the Fort Hancock area in late 1919 and wanted water delivered through the system was told in no uncertain terms that his lands could only be served "on a *temporary* basis from surplus stored

water."[72] [Emphasis added.] This temporary status was made abundantly clear in internal correspondence, which demonstrated Reclamation's intent to operate the Project as efficiently as possible and not to let excess water run to waste once the Project was fully operable and acreage fully developed: "As far as possible the amount of water wasted at the lower end of the Project will be kept at the lowest possible minimum."[73] In fact, when the Chief of Construction for the Rio Grande Project wrote to Reclamation director A.P. Davis to address the Fort Hancock landowner situation, he wrote: "As only about one-half of the [project] irrigable area is now in cultivation, there is during the year 1920 and *may be* during some future years, some excess water available in the Elephant Butte Reservoir which might be used on other lands *temporarily*, provided the rental of this water under temporary contracts to these lands outside of the present and contemplated project limits does not involve the Service in a controversy which might prove of a serious nature when the water supply requires that

73 "Project Manager to Director and Chief Engineer," January 3, 1920.

delivery of water to these lands be discontinued."[74] [Emphasis added.]

Despite such apprehension, Reclamation executed a Warren Act contract a few years later with Fort Hancock landowners who were now organized under Texas laws as the Hudspeth County Conservation and Reclamation District No. 1, or "Hudspeth." The language of the Warren Act contract underscored the temporary and uncertain nature of the water supply, as well as the water's character, providing only "for the sale to the District [Hudspeth] of such water from the project as *may be available without the use of storage from Elephant Butte reservoir*, delivery to be made at the terminus of the Tornillo Main canal during 1925, and thereafter, during such irrigation seasons as established on the Rio Grande project."[75] [Emphasis added.] By 1924, the official annual Rio Grande Project histories described the Tornillo Canal's systemic function as "collecting waste and surplus waters throughout the project for use on Tornillo lands *and* for sale as surplus water to the recently organized Hudspeth County Conservation and Reclamation District No. 1."[76] [Emphasis added.] More about Hudspeth's development and role in the Project is described in several sections below.

Completing the Rio Grande Project Construction

In addition to building the Project's primary delivery infrastructure, Reclamation Project officials soon recognized that other work would need to be completed to operate the Project efficiently. For example, in order to properly collect Project data moving forward, the agency found in early years that it had to conduct "farm surveys" in the Mesilla and El Paso Valleys, since so much of the land being watered had been part of Spanish land grants and consequently had non-existent or poorly described legal boundaries.[77] Additionally, as irrigated acreage expanded on the Project, farmers and Project engineers recognized that drains were going to be needed to prevent Project lands from becoming swamped, a problem that was also occurring on other projects across the West.

Nevertheless, by the mid-1920s, the Project was functioning smoothly, with Elephant Butte storing water for the farmers, and various diversion dams and canal headgates completed and delivering said water to the farmers during the irrigation season. Having started from an incomplete and inefficient preexisting system comprised of hundreds of community ditches and multiple headings on the river, the farmland stretching from the Rincon Valley in the north to the Hudspeth County line in the south was now receiving a more dependable supply of water than ever before, and irrigated acreage was increasing as a result. However, although much of the basic Project infrastructure was in place, continuing efforts to improve water delivery efficiency meant that the Project as a whole continued to evolve indefinitely.

Chapter 2: Project Operation and the First Rio Grande Compact

With the international water crisis with Mexico averted by the signing of the 1906 Treaty and the near complete buildout of the major Rio Grande Project infrastructure, irrigation-minded people again turned their attention to the potential for new reclamation and development projects on the river. The demands on the waters of the Rio Grande never ceased. Whether they originated downstream of the Project as they did with the Hudspeth District, or upstream of the Elephant Butte Dame in northern New Mexico and Colorado, supply seemed always to be outstripped by demand. However, with the Project infrastructure having changed the river system so dramatically, officials contemplated whether the development embargo that had been imposed in 1895 could and should be withdrawn. As early as 1919, engineers saw the potential for an irrigation and drainage project upstream from Elephant Butte in a section known as the Middle Rio Grande Valley.[1] Other engineers were examining development potential even further upstream in Colorado's San Luis Valley, too. The existing embargo precluded them both. With the unceasing demands on the river from every segment, however, the three states (Texas, New Mexico, and Colorado) recognized that a permanent agreement to apportion the river's resources was necessary. Knowing that any new irrigation project would cause dissent among water users, Colorado and New Mexico Legislatures adopted laws granting permission for the states to negotiate an interstate compact for the division of Rio Grande waters between them.[2] Texas, concerned about upstream projects' effects on their downstream users, joined the group shortly thereafter. Compact discussions began in 1925, but it wasn't until February 1929 that the three states signed a temporary agreement, or truce, designed to last for six years.[3]

Downstream Lands and Hudspeth's Relationship to the Rio Grande Project

In 1919, as engineers began discussing the possibility of more irrigation development on the Rio Grande, water users located south of Elephant Butte Dam inevitably felt threatened by the proposed development of upstream lands. However, not all the lands downstream of Elephant Butte were included in the Rio Grande Project, and therefore not all had an equal claim to its water. In fact, there was a distinct difference between Project lands and non-Project lands, and a significant gap between their respective credibility in fighting upstream developments. In particular, neither the Reclamation Service nor the two Project irrigation districts (EBID and EPCWID) quite knew how to handle the Fort Hancock/Hudspeth farmers once that group rejected Project status.[4] While the Hudspeth farmers' concerns about upstream development were the same as those of the

Project districts', their refusal to officially join the Rio Grande Project put all the leverage for water delivery in the hands of the Project irrigation districts and the Reclamation Service. Unlike the Project irrigation districts, which could make a legal claim to water based on the Reclamation Service's filings of 1906 and 1908, Hudspeth had no such claims to the river's water, only to the Project's waste. Although the Reclamation Service was generally invested in providing water to as many acres as possible, engineers had already reduced the actual Project's estimated fully developed acreage to 155,000 acres, based on the finite water supply and the lack of Project efficiencies. Thus Hudspeth's contracts for rental water were made one year at a time in order to prevent any unrealistic expectations of water delivery, leaving the farmers of that region little to stand on in the discussions of upstream use.

In addition to having an unreliable year-by-year water delivery contract, the Hudspeth District also lacked a consolidated diversion structure, making the delivery of the quantity of water they needed very difficult and further imperiling the region to increased upstream usage. In the earliest years of Hudspeth's contract status, Reclamation delivered water to Hudspeth directly in the riverbed, with Project drains dumping excess water at the end of the Project back into the channel only to be re-diverted further downstream. For Hudspeth's many ditches to physically receive the water, however, Reclamation had to release excess supplies from Elephant Butte so that the volume was big enough to reach into the ditch headings. Although the 1911 Warren Act under which Reclamation executed contracts with water users did anticipate that so-called "excess" water from Reclamation projects could be made available for sale by the Secretary of Interior, it seemed unlikely that such an excess would exist permanently on the Rio Grande Project. As such, correspondence between the Reclamation and Hudspeth as well as language in each contract consistently placed Hudspeth in the position of subordination, due precisely to the uncertain supply of water. Uncertainty aside, parties worked together to solve the problem of inefficient delivery by determining that the extension of Project infrastructure – the Tornillo Canal – would help matters. By extending the Tornillo Main Canal into the Hudspeth District and contracting with Reclamation for the use of the waste water that came through this canal, Hudspeth water users would solve two serious problems:[5] they would obviate the need for excess storage water released into the river bed, and, because Tornillo's diversion was upstream from where the river became the international boundary, they would also prevent illegal Mexican diversions of their water supply on the Mexican side of the river across from Hudspeth's lands.[6] Nevertheless, the infrastructure changes were not enough to solve the unreliable water supply the district faced by not being part of the Rio Grande Project.

In 1923, Reclamation directed Hudspeth landowners to take some action "which would make unnecessary the enormous waste of water on the Project, which could not be continued in case of low water years or with the increasing area of the original Project being put in cultivation."[7] Later that year, Reclamation's chief engineer

wrote to the Commissioner of Reclamation that "until it has been demonstrated that less water than heretofore assumed is required, or that the return water from the El Paso Valley area will be of such quality as to permit its use without large waste of storage for dilution therefor for irrigation purposes, it is believed inadvisable to include any large area of additional land in the Project, or agree to supply water to lands outside the Project, by which farms will be developed depending on this water supply, which must later be discontinued, thus resulting in large losses to the owners."[8] Having realized their 1918 mistake of not joining the Project when they had the opportunity, the Hudspeth farmers now approached the situation another way, proposing to merge with the El Paso County Water Improvement District No. 1 and become part of the Project through that entity.[9]

Such a merger would entail expanding the irrigated acreage under the Rio Grande Project, however, and Project officials now recognized that the Project's supplies were already stretched to or even beyond their limits by the 1920s. Both Project districts (EBID and EPCWID) balked at the suggestion,[10] with Reclamation arguing against the proposal to include Hudspeth on the districts' behalf. Reclamation made clear that "it is absolutely impossible to continue present methods of water delivery...because of the large waste which such method necessitates."[11] Project Manager L.M. Lawson explained it this way in 1923: "Assuming that the entire project water supply is sufficient for 150,000 acres, which area is nearly approached by the present limits of the irrigation district for New Mexico and that of Texas, the inclusion of the Fort Hancock area on the same basis, insofar as permanent water right is concerned, is obviously impossible. In the determination of the Project water supply, however, the recovered water from the Juarez and El Paso valleys below the International Dam [aka the Acequia Madre's diversion dam] was not included. Irrigation of these sixty or seventy thousand acres will undoubtedly provide a run-off which, if properly collected, would probably supply irrigation demands for the area now in cultivation in the Fort Hancock district." Because the Project was still incompletely developed, however, it was "difficult to determine the actual present water status for areas outside of the present project limits."[12]

Tellingly, although a 1923 draft of the base contract – outlining the key obligations and how water delivery and payment would be determined each year – allowed for surplus water that had been stored in Elephant Butte Reservoir to be provided to Hudspeth when return flows and wastewater were insufficient, and when Elephant Butte Reservoir spilled.[13] But newly appointed Reclamation Commissioner Dr. Elwood Mead, one of the world's

foremost experts on irrigation development, expressed concerns over this language. When commenting on the first draft of a contract with Hudspeth, he opined that the document appeared "to provide a permanent right," and that it was "quite unlike any other water contract heretofore made by the Government." Mead offered the opinion that if the contract was executed as written, lands would be permanently developed, "with the thought that this contract provides for a permanent and substantial water right."[14] He urged against such language, clearly recognizing that Hudspeth had no such guaranteed right to the waters of the Rio Grande. As a result, the government would only sign a contract in which this clause had been deleted, leaving only wastewater in the contract. That version of the contract was signed in December 1924. The Secretary of Interior himself was even involved, writing to farmers in Hudspeth to let them know that "such flow as has been available at the lower end of the project during the past year of large upper river discharge cannot be maintained in future years of full project development and low water periods."[15]

Since 1924 then, the Hudspeth District has operated as a wholly separate entity apart from the Rio Grande Project and has only enjoyed contracts for Project return flows and wastewater,[16] with no guarantee to the district for any water at all. From the start, the contracts between Reclamation and Hudspeth were for seepage, waste, and return flows recovered from the Rio Grande Project and delivered to the district at the terminus of the Tornillo Main Canal and delivered into the Hudspeth Main Canal at that point; the historic record is replete with documents stating this intent and noting that Hudspeth farmers were not entitled to *any water*. Project Superintendent Lawson further assured EPCWID's manager Roland Harwell that any quantity furnished to Fort Hancock would be "on a surplus basis and subject to prior project demands,"[17] with Reclamation's chief engineer agreeing and stating that, even if the Tornillo Canal were extended to the upper end of the Hudspeth lands, that it "be understood…that no water can be turned out of the Elephant Butte Storage for its [Hudspeth's] benefit."[18] Thus, Hudspeth's 1918 refusal to join the Rio Grande Project remained irreversible.

The base contract negotiated at the end of 1924 was essentially for *water rental* during each irrigation season starting in 1925, and stipulated that the rental was "secondary and inferior" to the rights of Rio Grande Project lands.[19] The Hudspeth District agreed to pay for the water on a per acre-foot basis, with the Secretary of the Interior fixing the specific charge every year to correspond to 6% of the construction costs for any Rio Grande Project works that directly affected the district, plus a proportionate amount of the yearly operation and maintenance fees associated with those works. The contract did not represent a permanent right to these waters, and the United States was not obligated to deliver *any* amount of water. Instead, the Project retained the right to use this wastewater itself, and the Reclamation Service made it clear that it had plans to develop and manage the Project to a degree of efficiency such that eventually there may be no wastewater at all.[20] In commenting on the final contract

language, Hudspeth's own attorney, Major Richard Burges, noted that whether they liked the language or not, the district had "not a vestige of right in the waters of the Rio Grande," and so the district had to accept the contract words.[21]

The requirement in the December 1924 "base" contract that a cost be negotiated each year caused a great deal of headache for all parties in the two ensuing decades, which will be discussed at some length below. However, even with the several recurring issues and sticking points surrounding Hudspeth's water supply and water contract, the Project districts and the federal government never wavered from the position that Hudspeth's claim to water was always subordinate to and subject to Project operations and thus Hudspeth was much more vulnerable to upstream development than were Rio Grande Project participants.

New Rio Grande Development and Revocation of the Embargo

Meanwhile, continued westward migration throughout the young 20th century had put ongoing pressure on the upstream resources of the Rio Grande. The San Luis Valley in southern Colorado remained a magnet for agriculturally minded citizens thanks to the fertility of its soil. However, the valley had begun to experience major drainage problems due to the over-application of water on the lands. In the San Luis Valley, the problem was particularly acute, since land in the northern end of the valley sat in what was known as the Closed Basin, the geology of which let very little water drain back to the riverbed. Therefore, neither irrigated acreage nor production in the valley had increased as a result of growth, but instead had declined, as more and more land became seeped and alkalized and water applied to the land had unfortunate effect of raising the water table and/or evaporating.[22] The solution, proposed by Colorado's Irrigation Engineer Ralph I. Meeker who reported on the area in 1919 and again in 1924, was to drain the area and conserve the recovered water in a storage reservoir. His proposal would reclaim the swamped lands and provide a reliable supply of water to the San Luis Valley as well as the Middle Rio Grande Valley, just south of the Colorado/New Mexico border.[23] Meeker argued in 1919 that his Colorado storage project could proceed "without injury to the Rio Grande Project water supply or the Mexican treaty obligation."[24] (Emphasis in original.) Still, the Colorado engineers did not have a clear understanding of the hydrogeology of the basin until the late 1920s, and downstream users were skeptical of Meeker's assurances.[25] Meeker nevertheless advocated the revocation of the federal embargo that had been in place since 1895 and Colorado engineers began developing plans for several Colorado reservoirs including one called the Vega-Sylvester, high in the basin.

Just downstream of the Colorado/New Mexico border, residents of the Middle Rio Grande Valley saw development potential in their own region, as well, and were frustrated at having been deprived of water by "vigorous development in Colorado above and the Reclamation Organization below."[26] A 1919 report written

at the same time as Meeker's Colorado study had hinted at possible avenues for development in this valley and residents were eager to pursue this development further.[27] Following the establishment of the Rio Grande Compact Commission in 1924, the New Mexico Legislature appropriated $25,000 for a cooperative investigation between New Mexico and the Reclamation Service to study and report on the irrigation development and water supply of the Middle Rio Grande Valley.[28] Reclamation Engineer Homer Gault issued a detailed report on a potential Reclamation Service project in the Middle Rio Grande Valley in 1924.[29] Similar to lands in Colorado, Middle Rio Grande lands were suffering from a lack of drainage, rendering many of them swamped and not susceptible to cultivation; the water table in more than 90% of the valley had risen to a depth of less than four feet.[30] According to a New Mexico engineer who assessed Gault's report during compact negotiations in 1925, the combination of seeped lands and increased Colorado diversions had reduced irrigated acreage in the Middle Rio Grande from a high of 125,000 in 1880 to 40,000 acres in 1925. He said that the middle valley was 200,000 acre-feet short of its necessary water supply, but assured downstream users that reverting to irrigation of the full 125,000 acres in the Middle Valley would not "endanger nor injure" the water supply of basins further south.[31] Furthermore, Middle Rio Grande development proponents believed that a great deal of return water would be developed and usable downstream of the middle valley if a Middle Rio Grande project were to move forward.[32] The New Mexico engineer believed that the newly formed Rio Grande Compact Commission could, by allowing for development of the Middle Rio Grande, correct the injustices heaped upon New Mexico over the years by upstream users and provide "the general defense of its entire water rights wherever endangered."[33]

Just a few months after the engineer issued his report, on May 20, 1925, Secretary of Interior Hubert Work did in fact revoke the longstanding embargo. Work's action cleared the way for reservoir right-of-way applications in Colorado and New Mexico and it wasn't long before applicants submitted proposals for the Vega-Sylvester Reservoir and others in Colorado, as well as for Gault's proposals for storage for Middle Valley users. Contemporaneously, the New Mexico Supreme Court affirmed the constitutionality of the Middle Rio Grande Conservancy District (MRGCD), clearing the way for a development project to take place in that region.[34]

Unsurprisingly, the specter of new development reignited latent hostilities between the three Rio Grande states. There was a great sense of urgency to construct new projects, since Secretary Work's order reversing the embargo was accompanied by a stipulation that abrogation of water rights would occur if proposed developments were not completed within five years.[35] Colorado's reservoir construction plans, therefore, in combination with New Mexico's middle valley project, brought the promise of an interstate lawsuit. It was unclear whether New Mexico would sue Colorado, with Texas acting as intervenor, or if Texas would file the original suit against both upstream states. Regardless, the threat of an interstate battle to prevent further upstream depletions on the river loomed.[36]

Despite the threat of litigation, water engineers found themselves extremely busy gathering data, assessing plans, and preparing for construction in all three states. Colorado was intent on building the Vega-Sylvester Dam for which it had received a right-of-way from the federal government but was also investigating the Wagon Wheel Gap Reservoir. This alternative reservoir, located about 70 miles downstream from Vega-Sylvester, had more support from Texas and New Mexico because it would have a larger capacity and would provide better flood control to the two lower states than the Vega-Sylvester Dam.[37] Meanwhile the Middle Rio Grande Project seemed to garner the support of both Texas and New Mexico, which both accepted the conclusions of studies proclaiming that "re-habilitation of the project will improve the river regimen and conserve water."[38] On that project, Chief Engineer Joseph Burkholder's final report to the MRGCD suggested that drainage of the Middle Valley lands would result in the irrigation of a net 129,000 acres of land, restoring the area's previous productivity.[39] Through construction of a storage reservoir called El Vado on the Rio Chama (a tributary of the Rio Grande located just south of the Colorado-New Mexico State line and northwest of Santa Fe), Burkholder asserted that the Rio Grande's flow could be regulated, with flood protection provided in the spring and water available during irrigation season, as well.[40] Importantly, Burkholder concluded that Middle Valley development would "not infringe on the water supply for lands dependent on the Elephant Butte Reservoir."[41] Earlier studies had reached the same conclusion.[42] With what appeared to be widespread agreement on the value of the MRGCD Project to the upper basin at large, the focus remained on Colorado's development plans. Tension over Colorado's development made clear that the Rio Grande states needed a system that would permanently and equitably divide the river before additional projects moved forward. The recent conclusion of the Colorado River Compact in 1922 provided a model to these three states as they continued to tussle over the Rio Grande. (See map next page).

Negotiating the Truce

As engineering plans moved rapidly forward in all three Rio Grande states, the Compact Commission remained largely out of the process. Following brief negotiations between only New Mexico and Colorado early in the commission's existence and the joining of Texas in 1926, several months of intensive data collection by engineers followed. Then, the commission was inactive for several years.[43] By the summer of 1928, the commission had made a little progress toward negotiation of a truce, but major disagreements remained.

Speculation was rampant about what each state would demand at an interstate negotiation. MRGCD engineer R.G. Hosea predicted that Colorado would argue for a specific volume of water delivered at the Colorado/New Mexico state line, leaving Colorado officials to otherwise independently manage the water within state boundaries.[44] Hosea believed, however, that downstream parties would only agree to such a position if Colorado built a reservoir on the state line to guard "against shortage to lower interests, keeping it full in intermediate periods,"[45] a concept that became known as the State Line Reservoir. The idea behind constructing a storage facility on the state line was that the state would store excess water "below any possible diversion by Colorado," ensuring that lower states would receive their share of the resource. Without such guarantees, Hosea doubted whether a treaty or compact could ever be achieved.[46] New Mexico and Texas, meanwhile, favored a division of water based on proportionate flow. New Mexico consulting engineer D.C. Henny proposed a delivery schedule for Colorado in an elaborate table of monthly surpluses and shortages, a method to which Meeker and other Colorado engineers objected, believing that the "inelastic" schedule would impose an impossible burden on Colorado during periods of shortage as well as unfairly restrict San Luis Valley development.[47] Because

their recommended method presented potentially insurmountable problems, the two downstream states alternatively suggested that calculations be based on the amount of water in Elephant Butte at any given time as well as the meeting of MRGCD's water rights. In other words, if Elephant Butte was full, Colorado would have few restrictions on use (other than obligations to MRGCD), and conversely, if it were empty, lower states would demand all discharge feasible from Colorado.[48] Colorado's response to the proportionate flow discussion was to suggest a schedule substituting calendar year flows for monthly flows, as well as a period of ten years for calculations, a method to which Texas and New Mexico objected since it gave Colorado an uncomfortable amount of flexibility in meeting the terms of any proposed compact.[49] There seemed to be no outward agreement during this speculative phase of negotiations.

The proposals and speculations were, however, moving the agreement process forward. By the time the parties met in January 1929 to work out the details of what was now thought of as a temporary compact, Colorado had agreed not to deplete the Rio Grande's flow at the state line for the life of the compact and to furnish water to the Middle Valley, *if* it was permitted to construct a Closed Basin drain in the San Luis Valley, the intent of which was to free up the water in the Closed Basin that was currently trapped. Colorado agreed with Texas and New Mexico that a State Line Reservoir – if constructed – would help to regulate flood flows for the downstream states, and all three states agreed that the Middle Valley should be permitted to divert or store water equivalent to any spill from Elephant Butte Reservoir. According to Hosea, the proposed compact, including the projects and conditions outlined above, represented no more than a "six-year cessation of hostilities," as opposed to a permanent solution.[50] Following several days of meetings in Santa Fe, the commission arrived at a draft compact, and each state signed it on February 12, 1929.[51]

Though called a compact, the document was more accurately a six-year truce, "during which period of time Colorado agrees not to impair the flow of the river by new or increased diversions or storage within the limits of Colorado, unless and until such depletion is offset by increase of drainage return,"[52] a reference to the Closed Basin drain, a compromise to which Colorado had only reluctantly agreed.[53] New Mexico was more positive about the compact and its potential to successfully guide the future development of the river. New Mexico compact commissioner Francis C. Wilson reported to New Mexico Governor Richard Dillon on the compact and spent a considerable amount of time explaining both the situation concerning the San Luis Valley's Closed Basin drain and the need for the State Line Reservoir, both of which were proposed in the compact. Wilson felt strongly that the construction of the drain from the Closed Basin of the San Luis Valley to the Rio Grande was feasible and would augment the flow of the Rio Grande by 175,000 acre-feet per year thereby providing "a steady and equated flow throughout the year" to downstream users.[54] Plus, for every bit of water returned to the Rio Grande at the state line by the drain, Colorado could use an equivalent amount without damage to

water users in the downstream states. Wilson argued that the drain would thus benefit both Colorado and New Mexico. As to the State Line Reservoir, Wilson explained that its construction would allow Colorado to deliver to the state line a regular amount of water regardless of the time of year and would thus make the most efficient use of the water in both states. This regulated flow would be of particular use to the MRGCD. Wilson concluded that the compact would lead to cooperation between the three states, would use the water of the Rio Grande the most efficiently, would maintain a set flow at the state line between Colorado and New Mexico for six years regardless of developments in Colorado, would avoid litigation, would lead to the drainage of the Closed Basin and thereby augment the flow of the Rio Grande, would lead to the construction of the State Line Reservoir and thereby stabilize the water supply in New Mexico, and would allow a more permanent compact to be drawn up in six years.[55]

Soon after the compact conference, Colorado's representative Delph Carpenter informed the commission that even though Colorado's representatives had signed the draft compact during the meeting in Santa Fe, the state government would not sign the document to make it final. The upstream state had developed two major concerns about the draft. First, the draft compact required Colorado to deliver a monthly volume at the Colorado/New Mexico state line based on data that included an era when Colorado's San Luis Valley was far less developed, and therefore less water-hungry. State officials believed these data unfairly represented the current situation. Second, Colorado's studies had demonstrated a large volume of water being wasted at the downstream end of the Project, a fact which historical research has proven to be true. Colorado felt that it should not be asked to conserve resources when so much water was being allowed to flow out of the Project unused.[56] Consulting engineers for the downstream states took issue with Colorado's stance. They maintained that Colorado could simply not be permitted to increase its water use unless the water supply was augmented from another source, such as a sump drain in the Closed Basin or more efficient drainage in all of Colorado's swamped areas.[57]

In the days following Colorado's announcement that it had backed out, compact commissioners altered the compact's final language so that all three states would find it acceptable, which they ultimately did, and signed. Most important, perhaps, was the inclusion of Article V, which established that Colorado "must not cause the flow at the State line to be depleted."[58] Although the article lacked the specificity desired by the downstream states, all parties knew that construction of the Closed Basin drain and the State Line Reservoir in the ensuing years would be critical to reaching permanent compact terms in 1935, when the temporary compact was set to expire.[59] All three states began to lobby the federal government to include funding to construct the Colorado infrastructure as part of the bill ratifying the compact. They argued to federal representatives that funding the State Line Reservoir should be seen by the government as compensation to American water users for the water the United States promised to Mexico in the 1906 treaty,[60] since that treaty had "permanently deprived these

states of the use of that amount of water for their development."[61] The animosity between the states aside, they were united in asking the federal government to ratify the compact and to help fund the infrastructure its success relied upon.

The federal government seemed set to comply with the Rio Grande states' desires when opposition came from what was now known as the Bureau of Reclamation, or the former Reclamation Service. The head of that agency, Commissioner Elwood Mead, did not like the compact terms, and he also did not like the federal bill proposed to ratify it, the draft of which included federal funding for Colorado's infrastructure. In Commissioner Mead's words, the compact was meant only to be a "temporary expedient" in which Colorado agreed not to "cause or suffer the water supply at the state line of Colorado and New Mexico to be impaired by new or increased diversions for storage within the limits of that state," unless those depletions were offset by drainage returns and/or until the State Line Reservoir was constructed, but no later than June 1, 1935.[62] Mead did not like that the compact held his agency hostage and demanded financial support from it, nor did he believe that the compact did the job that a real interstate compact should do. He persuaded Secretary of the Interior Ray Lyman Wilbur of his beliefs, who subsequently informed Congress of his own opposition on the same basis. Additionally, Wilbur noted that the bill and the compact generally provided "for Federal expenditures for reimbursement of which no provision is made, and of a character which would set an undesirable precedent."[63] In the end, Congress passed the compact into law without the provision for federal funding of Colorado infrastructure. Without funding, and to the dismay of Rio Grande water users who were hopeful about the potential for an augmented supply, no State Line Reservoir was ever constructed.

Nevertheless, with a temporary compact in place and ratified into law, many downstream users could be more confident that upstream diversions would not radically affect their irrigation practices. The compact would allow for Rio Grande Project water users to continue receiving the same allotments of water, and Middle Valley residents had hope that their developments would soon enhance the irrigation of their own valley without interference from Colorado users. The Hudspeth District, however, remained in limbo. Their status as contract-users of excess Rio Grande Project water was not in any way protected by the temporary compact and as use of the river increased there was likely to be less "excess" than ever before.

Chapter 3: The First Compact Era: 1929-1935

Implementing the Compact

Regulating a river in the midst of a worldwide economic depression and in the face of interstate and international tension was a challenge. Little did anyone know when they signed the 1929 Compact how dramatically the world would change that October. Nevertheless, the 1929 Compact – signed before the October 1929 stock market crash which launched the Great Depression – quelled immediate tensions between the states and provided temporary relief through various Compact articles that addressed each of their concerns, as well as through a requirement that maintenance of the "status quo on the river" be the primary consideration of this temporary Compact.[1] For instance, the Compact addressed Texas and New Mexico's concerns over Colorado's development through Articles II, IV, V, and VIII with Articles II and IV identifying the draining of the Closed Basin (and returning of that water to the river) to be of the utmost importance as a means of compensating Rio Grande users for waters given to Mexico in 1906 treaty. Then Article V prohibited Colorado from further depleting the Rio Grande until such depletions were offset by drainage returns, and Article VIII provided Colorado's consent for a storage reservoir to be constructed below the lower state bridge, i.e. just north of the state line in Colorado. As far as Colorado's concerns about water being wasted at the lower end of the Rio Grande Project, the Compact's Article III required New Mexico and Texas to establish and maintain gauging stations between Elephant Butte Dam and the lower end of the Rio Grande Project in order to monitor all releases, flows, distribution, and waste of water. Meanwhile, the Compact addressed Texas's concerns about New Mexico's water use in the Middle Valley in Article XII, which assured the other two states that New Mexico would not "cause or suffer the water supply of the Elephant Butte Reservoir to be impaired by new or increased diversion or storage within the limits of New Mexico unless and until such depletion is offset by increase of drainage return."[2] The clear language of the Compact dictated, however, that no future negotiations for a permanent compact were bound by any part of this document, which also meant that the negotiations leading up to it were quite distinct from those leading to the 1938 Compact.[3] Finally, because so much of the 1929 truce depended on the construction of both a drain and a reservoir in Colorado, it was not clear to any of the parties how the interstate dispute would be resolved if those projects never came to pass.

The river system was constantly changing as the Rio Grande Project neared complete development with regard to irrigated acreage as well as canal and diversion dam infrastructure. The Compact accounted for the river's changing behavior by demanding the acquisition of data. In addition to the articles described above, one of the provisions of the Compact was the creation of a Compact Commission, which was to meet annually and prepare an annual report while working towards drafting a more permanent compact. In order to draft this compact, the commissioners needed a better understanding of the ever-changing river. At the commission's first annual meeting, that body asserted that the clauses of the truce that demanded rigorous data collection were intended to "provide for the accumulation and preservation of such data as may be necessary to a final and definite apportionment between the signatory states of the use of the waters of the Rio Grande and its tributaries

above Fort Quitman, and for the purpose of enlisting the federal government in augmenting and stabilizing the stream flow, on account of deliveries of water to Mexico under treaty obligations."[4] The commissioners were in agreement at this first meeting that accurate water supply data would be "indispensable in the formulation of the final compact to which the present compact looks."[5] They also further noted – repeatedly over the ensuing years – that the "object of all Signatory states is to permit the maximum use and future development of the Rio Grande consistent with the rights of the respective states." It was clear that none of the states desired to permanently limit the uses of the river; to the contrary, each state wanted to maximize their uses within the limits of the law.[6]

As such, determination of data collection methods dominated the early years of the temporary Compact's implementation on the Rio Grande. The three states, with the cooperation of the International Boundary Commission and the U.S. Geological Survey, installed gauges and determined agreed-upon methods of measuring the river. Once those procedural issues were set, the collection and analysis of data (per Article IV of the 1929 Compact) began, with each member of the Compact Commission receiving identical data annually including daily gauge heights, discharge curves, and storage stage in Elephant Butte Reservoir.[7] With new gauges all along the river, there was more information available than ever before, despite dozens of previous investigations. Presumably, this new data would have helped all three states understand the river's behavior in light of developments along the Rio Grande over the previous several decades.

The three Rio Grande states used the opportunity of the new data sets to launch new analyses. One of the novel studies that emerged from the Compact negotiation data was published in 1931. Not surprisingly, the 300+ page report examined water use and geology in the San Luis Valley. New Mexico State Engineer Herbert Yeo led the study and examined all previous data collected, including investigations performed by Colorado's Meeker and Tipton, as well as the new data being gathered pursuant to the 1929 Compact. Recognizing that Colorado was awaiting entitlements to construct one of two reservoirs upstream – the Vega-Sylvester and/or the Wagon Wheel Gap, several miles downstream – in addition to the State Line Reservoir, Yeo's study found that construction of Vega-Sylvester (in the northern part of the San Luis Valley) would "seriously menace the water supply furnished by the Rio Grande to New Mexico," since he conjectured that all of the water stored would simply be consumed downstream in the southern part of the San Luis Valley and remain in Colorado.[8] If accompanied by a compact and guarantee, however, Yeo thought that the Wagon Wheel Gap site – located nearly 70 miles further downstream in the San Luis Valley – could be effectively used to regulate flow into New Mexico thanks to that proposed reservoir's greater holdover storage capacity. Yeo concluded that possible depletions associated with increased irrigation in Colorado posed "a future threat upon the water resources of [New Mexico] of such magnitude that it may seriously impair the agriculture dependent thereon."[9]

Compact parties were all too aware that the 1929 truce would expire in 1935, and that its temporary demand regarding Colorado's obligation to deliver the existing amount of Rio Grande water at the state line could be "renewed, abrogated, or changed."[10] New Mexico's Yeo hoped that when the parties negotiated a permanent compact, his state's compact representatives could use his data as evidence against any greater claims for water that Colorado might attempt to make. To no one's surprise, Colorado was also conducting its own investigation of conditions in the San Luis Valley, and Yeo suspected that the state would vie for even more water from the Rio Grande in the next round of negotiations, "regardless of the results [or impacts] south of the State Line."[11] Yeo wrote that New Mexico and Colorado engineers did not and could not see eye-to-eye on these issues and that "there is small chance of an amicable agreement as to facts and prospects."[12] Yeo urged that before the 1929 Rio Grande Compact expired, New Mexico had to "establish that use of water in the San Luis Valley is wasteful, extravagant and needlessly injurious to water users on the lower Rio Grande."[13] Meanwhile, Colorado was also investigating downstream wastes by the Project, sending engineer R.J. Tipton and Colorado Commissioner M.C. Hinderlider Texas to measure the river at the Tornillo Gaging Station, the Tornillo Ditch, and the head of the Hudspeth County Canal in order to study potential waste at the southern end of the Rio Grande Project.

Meanwhile, in spite of their differences, all three states came together to lobby the United States to fund drain construction in Colorado. During the spring of 1933 representatives from New Mexico, Texas, and Colorado approached Congress to appropriate funds for both the construction of the Closed Basin drain and surveys for a reservoir along the Colorado-New Mexico state line. Delegations from Colorado and Texas travelled to Washington D.C. to persuade members of Congress in person of the need for construction of the Closed Basin drain.[14] Additionally, each state's governor and state engineer wrote to congressmen who sat on the House and

Senate Committees on Irrigation and Reclamation.[15] Finally, the Rio Grande Compact Commission's third annual report explicitly recommended the passage of legislation authorizing the construction of the drain[16] and all three state legislatures passed memorials that pressed Congress to fund the project.[17] (See map in Chapter 2 for locations)

In 1935, likely in response to this lobbying effort, the federal Public Works Administration (PWA) commissioned a study by engineers on the San Luis Valley Drain Committee regarding the feasibility and worth of the Closed Basin drain project. In the resulting report, authors O.V.P. Stout, F.H. Fowler, and E.B. Debler presented information on the cost, water supply, and water quality associated with draining the so-called "dead area."[18] Their work began with field investigations carried out in February 1935 that were aimed at revealing whether some of the projections about the Closed Basin drain were accurate. For example, proponents of the project asserted that the amount of water recovered by the drain would and should allow Colorado the freedom to pursue equivalent water development and storage projects in other locations. But the PWA investigation found that the early estimates on the amount of recoverable water from the drain were "greatly exaggerated," offering a picture of the project that was far too optimistic.[19] Further, they found it likely that the recovered drain water would in fact be used locally to bring more Colorado lands under cultivation rather than being released to the Rio Grande for downstream use as was claimed. For this reason, the authors wrote that "no regular dependence can be placed on [the drain] securing water in material amount" for downstream users because the overall amount of water that could be developed was less than that promised in the proponents' proposal. [20] Additionally, the authors noted that water quality, and especially salinity, had to be a significant consideration because the drain water was intended for irrigation use. By diverting the drain water to the Rio Grande and allowing Colorado to store an equivalent amount of water in the watershed's headwaters, the project would, in effect, replace fresh water entering the Rio Grande with already used, saline water for downstream users. While the quantity of water in the Rio Grande at El Paso might be unaffected by this trade, the salt content would increase by 3-5% at El Paso, a notable, but not critical, decline in the water's quality. Although this would "increase the menace

of salt" it would not "be on an extent to cause alarm," the authors concluded.[21] Despite lukewarm support, the engineers wrapped up by estimating that the project – at a cost of $580,000 – would recover an average of 40,000 acre-feet of water per year that would otherwise not drain into the Rio Grande, and that the drain water would not *significantly* alter the water quality of the Rio Grande in its lower stretches. The drain would "continuously salvage a considerable amount of water that is now lost," especially in years of high runoff[22] and that the project cost as well as the annual maintenance cost ($10,000) was "well within the economic value of such water in this territory."[23] Therefore they suggested that, if the United States paid for the construction cost as proposed, the annual maintenance fee that would be paid by farmers would be a worthwhile investment for San Luis Valley interests to take on.[24] However, the investigators made it clear that the drain would be unlikely to augment supplies for users in downstream states.

Despite the generally positive federal recommendation, the United States did not invest in the drain and the drain was not constructed. The onset and deepening of the Great Depression was at least one reason for inaction during the years that the river was regulated by the 1929 Compact. Regardless of the reasons for inaction, as the deadline for the Compact's expiration neared without any implementation of the solution supported and advocated by all parties in 1929, panic set in for the three states. Exacerbating the already tense situation was a period of low water on the Rio Grande in 1934 and 1935,[25] as well as the geographic proximity of what became known as the Dust Bowl, which affected all three Rio Grande states. While that devastating set of circumstances was not directly related to the Rio Grande, it nevertheless served as a constant reminder of the Rio Grande Basin's overall scarcity of water. Parties intensified their studies of the basin around 1935, so they each would have a better understanding of the situation and data for the battles to come. Some of these studies revealed that the amount of water in Elephant Butte Reservoir at the beginning of the 1935 season was less than half the average amount held by the lake in the previous 15 years.[26] In response to the shortage, some water users began to seek new sources of water, others abandoned their lands, while still others looked upstream to find a scapegoat for the shortage.

Hudspeth Water in the Inter-Compact Years

The data revealing the shortage in Elephant Butte was the latest in a string of events that led farmers downstream in the Hudspeth District to unite in seeking a more reliable source of water. In addition to the water supply shortage from the Project, Hudspeth was also competing with Mexican farmers who were diverting excess water from the Rio Grande below the Acequia Madre diversion and across the border from Hudspeth lands. They approached their water insecurity in two ways. First, they aimed to change the language of their 1924 base contract with the Bureau of Reclamation, and when that raised eyebrows, they tried to officially join the Project again. Both efforts failed.

Hudspeth had begun discussions to renegotiate its contract with the Bureau of Reclamation in the late 1920s, when farmers in the district began to suffer from seeped lands and demanded drainage to maintain production. Hudspeth had been late in its payments to Reclamation for the 1929 water year, a circumstance that had become

common under the stipulations of the original contract, and during the annual negotiations over new rates, the parties batted around the idea of signing a new base contract in order to avoid similar disputes in the future. Hudspeth proposed a new contract in February 1930 which contained simple language in Section 4, stating that "the United States will have available at the terminus of said Tornillo Main Canal, certain water developed from the Rio Grande project." In Section 6, the proposed contract simply stated that the United States, "will deliver to the district at the terminus of the Tornilla [sic] Main Canal during each irrigation season as established on the Rio Grande Project, such water as may be available at said terminus without the use of storage from the Elephant Butte reservoir, and as may be required for the proper irrigation of district lands."[27] As prospects for infrastructure development in Colorado under the 1929 Compact declined and awareness of Elephant Butte's water shortage emerged, Hudspeth farmers were under even greater pressure to act. However, several recurring issues and sticking points made the renegotiation process difficult, leaving issues that remained unresolved by the time the Rio Grande states signed the permanent 1938 Compact.

The first difficulty Hudspeth encountered in renegotiating its 1924 contract was related to Hudspeth's repayment of Rio Grande Project costs. The way that Hudspeth's original contract was written, Hudspeth farmers reimbursed EBID and EPCWID a proportionate amount of their respective repayment costs to the United States,[28] depending on the volume of water those districts supplied to Hudspeth. One of the negotiating points for a new contract was whether Hudspeth should have to pay construction, operation, and maintenance fees for the entire Rio Grande Project infrastructure or just for the Rio Grande Project drains in the El Paso area that fed the district its water. The issue boiled down to the origin of Hudspeth's water: was it water that had been stored in Elephant Butte, meaning that the district should help pay for the dam's construction; or was it water derived from Project drainage in the El Paso Valley, and Hudspeth was off the hook for Elephant Butte costs?[29] The Hudspeth District argued that the benefits of Elephant Butte Reservoir's storage were expressly omitted from the 1924 contract, and therefore the district could not be expected to pay for the reservoir's construction, operation, and maintenance. The two Rio Grande Project irrigation districts, on the other hand, which benefitted from Hudspeth's payments offsetting their own, argued that the drains did not actually create a water supply, but instead allowed for the collection of water that was originally derived from Elephant Butte Reservoir.[30] As they saw it, Hudspeth owed the Project districts a greater offset.

The second sticking point also related to payment. Would Hudspeth be required to pay for all the water available at the end of the Tornillo Canal, regardless of their ultimate use of it, or could it get away with paying only for water that it used beneficially? Reclamation and the two Project districts argued for the former scenario, noting that if the contract obligated the United States to deliver all of its wastewater to Hudspeth rather than use it elsewhere, then reciprocity dictated that Hudspeth had to pay for it all.[31] The Hudspeth District, on the other

Elwood Mead, Commissioner," July 6, 1928, 115-54-A-81, Office of the Chief Engineer, Denver, Colorado, General Correspondence Files, 1902-1942, (Engineering), Rio Grande, Box. 1133, 249-T, Rio Grande, Hudspeth County Conservation and Reclamation District #1, 1928 thru 1930, U.S. National Archives, Denver.

30 "Roland Harwell, General Manager, to Mr. H.J. Devries, District Counsel," July 12, 1928, Entry 7, General Administrative and Project Records, 1919-1929,Project Files,1919-1929, Rio Grande 223.02- Box 908, 223.02 Rio Grande Lease of Water Contracts Hudspeth County Conservation & Reclamation Dist., Oct. 1927 thru Dec. 1929, 1 of 2 Transfer Case, U.S. National Archives, Denver.

31 "H.J.S. Devries, District Counsel to Commissioner, Washington D.C.," Memorandum: Water charges - Hudspeth County Conservation

hand, argued that it should be obligated to pay only for water that it used, not for water that simply flowed from the Tornillo Canal through the Hudspeth Main Canal and back into the Rio Grande, unused.[32]

The contract language Hudspeth proposed in 1930 concerned EBID farmers and the irrigation district's Board of Directors. When they met to discuss the issue, their actions indicated well-placed concerns regarding Hudspeth's efforts to usurp Project water rights. Specifically, EBID took issue with the language in the sections 4 and 6 (quoted above) and recommended changes that would better protect EBID's users and leave no doubt as to Hudspeth's secondary status. The language recommended by EBID is highly relevant to today's dispute and helps to discern the beliefs and intent of the EBID water users and their representatives. EBID farmers wanted to ensure that new Hudspeth contract language protected EBID users from any future Hudspeth claims to Project water. For Section 4, the EBID board thus recommended this substitute language, which put important words from the original 1924 contract back into the newly proposed contract: "Whereas the United States will have for disposal at the terminus of the Tornillo Canal certain water which represents *operating and unavoidable wastes* of the Rio Grande Federal Irrigation Project, as well as drainage water return from the lands of this project all of which water may be used for the irrigation of lands within the district." [Emphasis added.] EBID also recommended more precise language for Section 6 of the proposed new contract:

> The United States will provide for the uses of the District at the terminus of the Tornillo Main Canal and at other points where its diversion is possible into the canals and distributaries of the district and during each irrigation season as established by the Superintendent of the Project, such waste and other water from said project as may be available *without the use or release of stored water from Elephant Butte Reservoir specifically for the irrigation of district lands*. The Secretary of the Interior shall be the sole judge of the availability of such water unless and until the control of the reservoir shall pass into the hands of the waters [sic] on said federal project."[33] [Emphasis added.]

EBID also objected to another clause that they believed might leave room for misunderstandings in the future: "we do protest against the clause which reads: 'and as may be required for the proper irrigation of district lands.' This undoubtedly would leave a loophole," EBID's manager wrote to Rio Grande Project Superintendent L.M. Fiock, "for many future arguments and disagreements as to what water may be required for a 'proper irrigation.' It is conceivable that both quantity and quality of water might be brought in question." In other words, EBID objected to any language that could be interpreted as requiring Project districts to deliver a quantity designed to achieve a particular quality of water for Hudspeth irrigation.[34] Any water delivered to Hudspeth was explicitly secondary and not guaranteed.[35]

Recognizing EBID's concerns, Hudspeth proposed yet another alternative plan. Having engaged in controversial negotiations over rates every year since the first year of its contract with the Rio Grande Project, Hudspeth requested instead to officially become part of the Rio Grande Project so as to obtain government assistance with

its drainage construction and of course, to obtain a reliable source of water.[36] Reclamation Commissioner Elwood Mead expressed support for the plan but mentioned, not surprisingly, that the two Project irrigation districts were opposed to Hudspeth becoming a part of the Project on equal terms with their own districts.[37] With some optimism, Hudspeth formally proposed to join EPCWID.[38] Engineer Louis Hill, working on behalf of Hudspeth, suggested in October 1930 that Hudspeth be given a "first class water right and pay her full proportion of the cost of Elephant Butte Dam."[39]

Just a few months later, Project Superintendent Fiock wrote to the Commissioner of Reclamation and recommended that negotiations be suspended, with the Depression and drought having thrown Project operations into chaos.[40] Although Hudspeth negotiations and discussions continued throughout the 1930s, there was little progress. In 1935, Reclamation's Chief Engineer E.B. Debler wrote to Commissioner Elwood Mead to let him know that Hudspeth had again made additional attempts to secure a water supply, a "repetition of efforts made years ago." Expressing his disapproval, Debler continued that in the context of Rio Grande Compact negotiations (which had recommenced), "the set-back to Colorado irrigation through the [previous] construction of the Rio Grande project should not be amplified by the allocation of a water supply to the Hudspeth District. There is, of course, no objection to the district using the *waste waters* of the Rio Grande project, but it is very doubtful that the district can stay in cultivation if its water supply is so limited for the reason that the waste waters of the Rio Grande Project will become increasingly saline and of more erratic flow as the project attains a higher duty of water."[41] From Debler's and many other United States professionals' perspectives, it was imperative to keep Hudspeth at arm's length and to maintain that district's subservient water supply position.

Shifting Alliances: The Changes of 1935

In 1935, the political landscape along the Rio Grande began to shift. Several issues (set against the context of the Depression and the Dust Bowl) converged at once to cause panic in Rio Grande states. The driving force behind the panic was the temporary Compact's June 1935 expiration date and the need for a permanent apportionment of the river. Second, the MRGCD completed construction of its project, storing nearly 200,000 acre-feet of water

behind the El Vado Dam on the Rio Chama, a tributary to the Rio Grande, located just south of the Colorado-New Mexico state line and northwest of Santa Fe, leading to concerns that less water was being contributed to the main stem of the Rio Grande below the Colorado/New Mexico state line.[42] Third, illegal and unaccounted-for Mexican diversions continued to increase, the impacts of which were progressively more acute. Finally, the Hudspeth District's attempts to renegotiate its base 1924 contract threatened to require that more water be released from Elephant Butte Reservoir for downstream users. Together, these concurrent concerns created a firestorm on the Rio Grande, inciting new disputes between parties, challenging the status quo, and forging new alliances.

1929 Compact Extension

The problem of the expiring temporary compact was paramount. As it had done annually since 1929, the Compact Commission gathered on January 28, 1935. This meeting began with heated opening statements. When United States delegate S.O. Harper later reflected on it, he said that the Colorado delegation came to the meeting with a chip on its shoulder, carrying residual anger over the 1895 embargo and steadfastly refusing to entertain any permanent compact that would require it to deliver a specific volume of water to the New Mexico state line. In private conversations with the Colorado delegation, Harper informed the Coloradans that without a compact, the courts would have to get involved, a situation that everyone hoped to avoid. Meanwhile, Major Richard Burges, representing the Rio Grande Project districts, explained that New Mexico and Texas were unwilling to negotiate a permanent compact until the Closed Basin drain in the San Luis Valley was constructed. Harper suspected that the real reason for their reluctance was that they had simply not done enough compilation and analysis of data yet to support their case against additional Colorado water development and used the drain as a stalling tactic.[43] Regardless of reasoning, each state finally conceded to extend the existing agreement, realizing that a solution designed by the courts could result in a worse situation for any one of the states. Therefore, they agreed in mid-February 1935 to extend the current truce for two additional years to June 1937, believing that each state would act in good faith. In the interim, each state hoped to obtain research data collected by the other two states so that all of them would be working with the same information when they came back together to determine an apportionment.[44]

Development of MRGCD

Up until 1935, Colorado had long served as both New Mexico and Texas's primary target of blame for water shortages in the basin. But the 1929 Compact had required Colorado to cease development until the Closed Basin drain and State Line Reservoir were constructed, neither of which had yet occurred. And, while small developments had in fact gone forward in the state, Colorado had not permitted the development of any major storage projects, in accordance with the agreement. New Mexico, meanwhile, had permitted (with the informal approval of the other two states) the MRGCD project to move forward with work that involved draining the swamped lands inside that district's boundaries and completing the El Vado Reservoir on the Rio Chama in 1935. Of course, this work was not done in secret, but Colorado and Texas suspected that the project they had informally sanctioned in the 1920s had expanded beyond its original scope. To ensure that New Mexico was complying with Article XII of the 1929 Compact and not causing any additional depletions in the Middle Valley, representatives of EBID and EPCWID inspected the MRGCD project in July 1934. That inspection revealed that

44 "Richard F. Burges to Hon. William E. Clayton, House of Representatives," February 16, 1935, Box 2F470, Rio Grande Compact Commission Records, 1924-1941, 1970, Center for American History, University of Texas at Austin.

MRGCD had developed new, previously uncultivated lands rather than simply draining the previously cultivated (but now swamped) lands, an action which the Project districts believed was a violation of MRGCD's original approvals. When, in 1935, MRGCD applied for funding from the Public Works Administration for an additional 10,000-acre pumping project near Albuquerque, Bureau of Reclamation Commissioner Elwood Mead assured downstream users that Reclamation had given no approval for such additional plans.[45] In fact, although Reclamation had thoroughly supported the project's development, the agency's chief engineer E.B. Debler asserted that his previously given opinion was based on a certain scenario. He had opined that that the MRGCD's original plans would not harm the Rio Grande Project or the flow into Elephant Butte Reservoir, an opinion that had had been predicated on the assumption that MRGCD's developments would be "confined to the river bottom lands." If now it was shown that the MRGCD moved to cultivate previously uncultivated "virgin" lands, then "the conclusions heretofore reached can no longer be supported."[46] As such, the blame for perceived water shortages on the southern end of the Rio Grande Project in Texas was shifting from Colorado squarely to New Mexico.

Thus, the MRGCD's developments drove a new wedge between Texas and New Mexico, one that the United States' delegate to the Compact Commission S.O. Harper predicted would have to be the subject of a "sub-compact" between the two states.[47] Taking the issue up, Texas's new Rio Grande Compact Commissioner T.H. McGregor wrote to Thomas McClure, State Engineer for New Mexico on April 13, 1935, regarding the shortages that Texas believed the El Vado Dam on the Chama River was causing at Elephant Butte. McGregor noted that although all parties had previously assumed that the El Vado Dam would "conserve as much water through prevention of evaporation as it would store," meaning that it would not "constitute a diversion of the run-off" which normally flowed into Elephant Butte, this had not been the case for much of 1935, and the water supply of Elephant Butte had been "seriously impaired by storage of waters at El Vado Dam." Aside from noting the actual problems Texas believed that El Vado Dam was causing, McGregor also explained that the fact that El Vado Dam had impounded waters destined for storage at Elephant Butte constituted a violation of Article XII of the Rio Grande Compact, and proposed that McClure confer with all interested parties to make an arrangement that would not "impair the rights of the lower Rio Grande interests."[48] New Mexico's McClure took the issue directly to Chief Engineer Anderson of MRGCD, noting that, "I had planned to take this matter up with the new Interstate Stream Commission at their first meeting, but the date for this is so indefinite I have decided to forward a copy of the letter, and will appreciate a statement regarding the contents of same."[49] Anderson responded that the MRGCD would "do everything possible to bring about an amicable settlement of any differences which might exist between our District and those in the Lower Valley."[50] However, two weeks later, a more detailed response from Anderson to McClure explained that MRGCD had studied the matter of the El Vado Dam and had determined that Texas's protest lacked substantive support. The district saw "no basis for the statement that our works have in any way impaired the water supply of the Elephant Butte Reservoir."[51] In fact, Anderson asserted the returns from MRGCD drainage water had *benefitted* the lower valley since the beginning of such flows from

the middle valley in 1930. Anderson concluded his letter by writing that "no water was stored at El Vado prior to this year [1930], hence there can be no reason for a protest, considering drainage return over the past four years and also that being returned to the river during the current year."[52] Texas did not concur with this conclusion, and MRGCD's operations would continue to be contentious in the near-term future.

United States-Mexico Relations

In addition to domestic tensions along the Rio Grande in the mid-1930s, international strife between the United States and Mexico grew during these years, as well. As noted above, EPCWID water users were concerned over unauthorized Mexican diversions downstream of the Acequia Madre (where Mexico received its treaty water in Juarez, across from El Paso and just downstream from the Project's Franklin Canal) as early as the 1920s, and these concerns grew more acute into the 1930s as all farmers faced drought conditions. Rio Grande Project users as well as non-Project downstream farmers had gathered in 1926 to argue that Mexico's diversions violated the terms of the 1906 treaty between the two countries,[53] and in response, the American section of the International Boundary Commission collected data, making "extensive preliminary surveys, plans, and estimates and negotiating with the Mexico Section of the Commission for river rectification and flood control from El Paso to Fort Quitman."[54] River rectification and the associated infrastructure would play a very important role in water deliveries to American farmers on the Rio Grande and formed a significant backdrop to negotiations of the 1938 Compact. [See the history of the rectification project below in Chapter 5.]

The International Boundary Commission and the Bureau of Reclamation worked together on river issues, and in March 1935, the latter agency produced a report on Mexican canal diversions, written by Project Hydrographer W.F. Resch. Rio Grande Project Superintendent L.R. Fiock had directed Resch to use "available and estimated Mexican records," a river flow analysis, and water distribution records from El Paso to Fort Quitman dating from 1931 to 1934. While the data was not thought to be 100% accurate, the investigation still showed "that in 1932 a large increase in the diversions by the Mexican canals was made and has continued."[55] Resch accused Mexico of withholding the official Mexican diversion records because they showed "a much greater volume being diverted than is allowed in the treaty of 1906."[56]

Resch believed that one of the most significant challenges of administering the river was that there had never been a way to measure or control the 60,000 acre-foot treaty delivery obligation to Mexico. The Acequia Madre – located just downstream but nearly across from the Franklin Canal and in the vicinity of El Paso – did not have a controlled intake or headgate of any kind. This uncontrolled intake "seriously interfered with the operation of

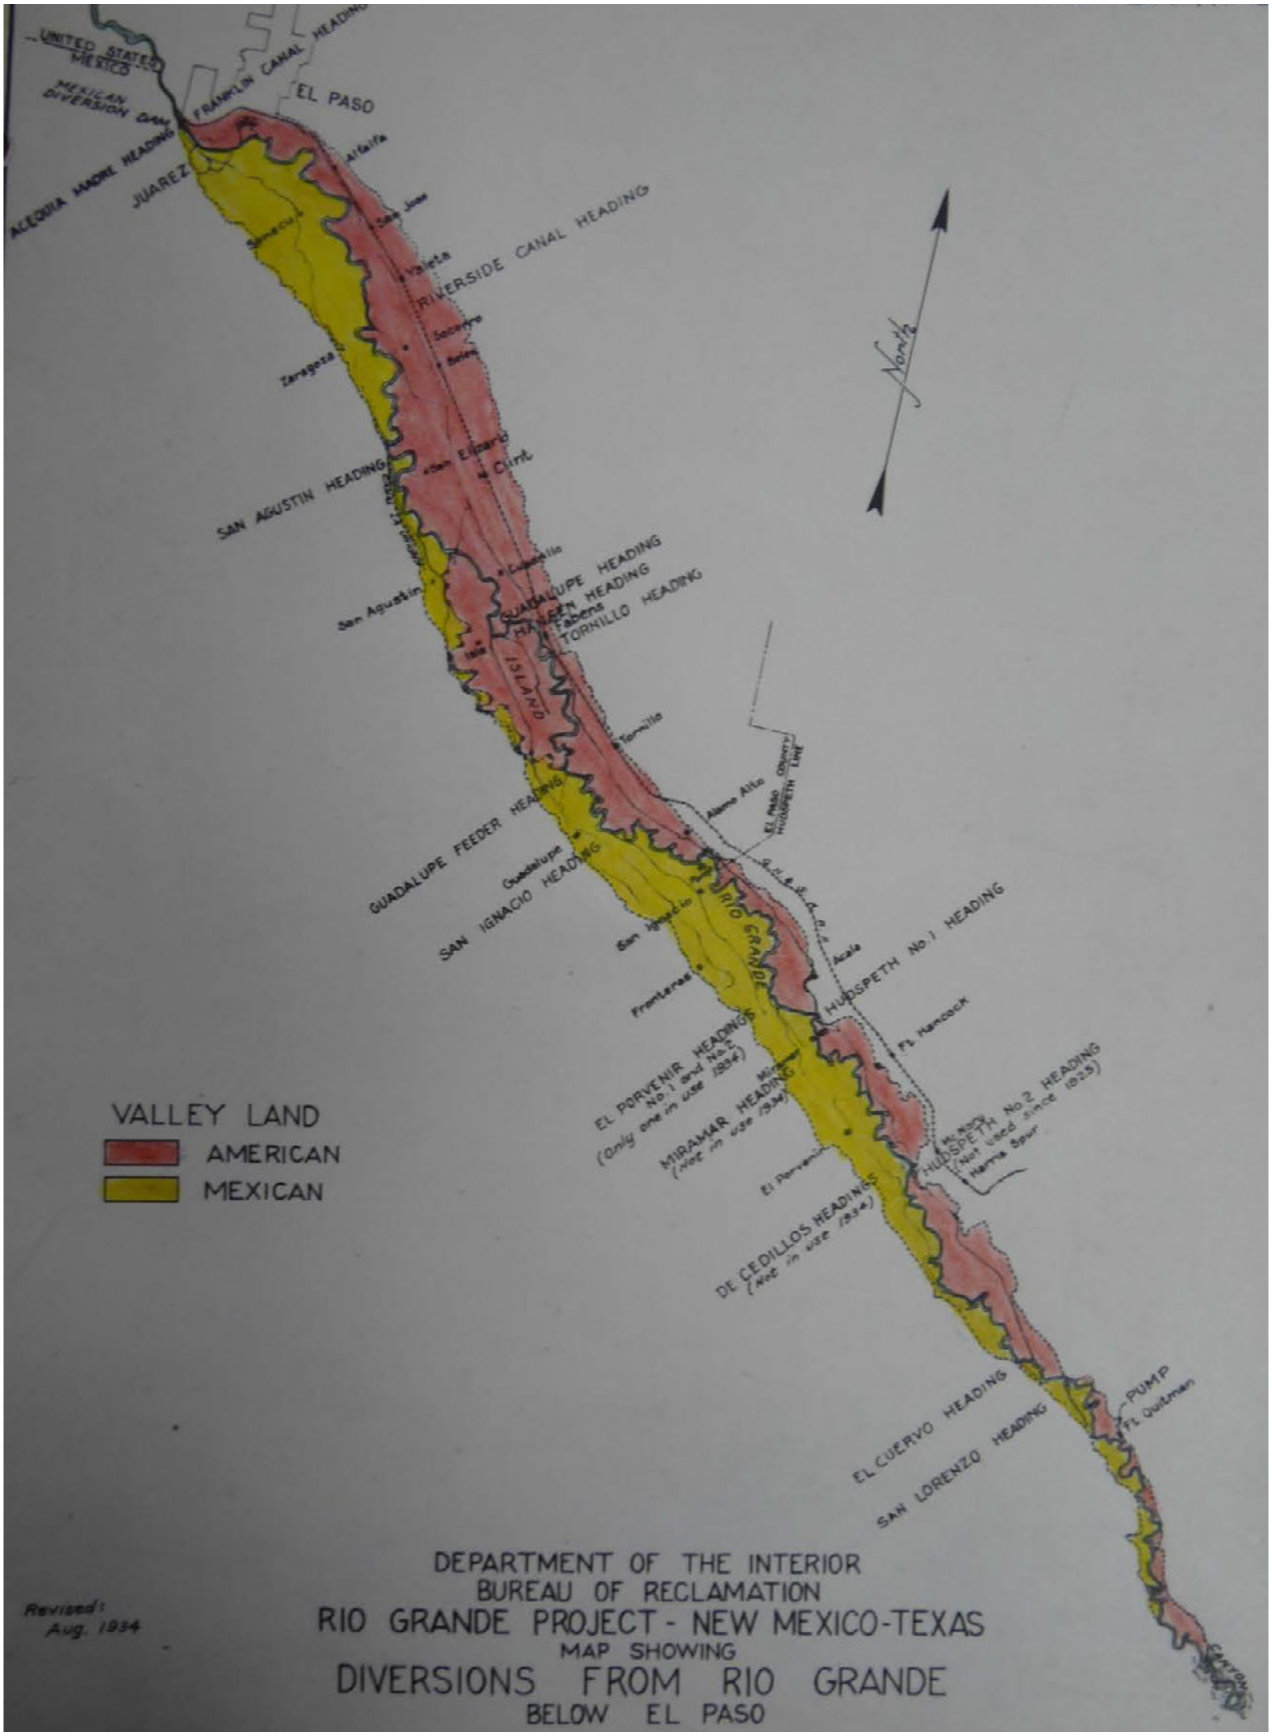
54 "Project History: Rio Grande Project, Calendar Year 1928," n.d., 15–16, NM OSE Library.

55 W. F. Resch, "Mexican Canal Diversions in the Vicinity of El Paso, Texas" (El Paso, Texas: Department of the Interior, Bureau of Reclamation, Rio Grande Irrigation Project, March 29, 1935), Engineering and Research Center, Project Reports, 1910-55, Code 510 Box 722, Mexican Canal Diversions in the Vicinity of El Paso, Texas, U.S. National Archives, Denver. This report is unpaginated.

56 The report was accompanied by a letter from Resch to Fiock in which Resch admitted that he was "not greatly impressed with the absolute accuracy of the conclusions" in the report, given that he had amassed discharge records from various different canals, wasteways, drains, and gauging stations, and combined them with evaporation, transpiration, and seepage estimates over a stretch of river 136 miles long. Resch guessed that the wasteway figures, based on ditchriders' estimates, were probably the source of the largest amount of error. Another large source of error was the lack of information on drainage water in the upper Juarez Valley, especially from 1932 onwards, a time period in which there had been much drain construction but little data collection. Resch was also hesitant because of "very meager data on the diversion and use of water" in the Juarez Valley. Despite all this, in his letter to Fiock Resch argued that the investigation data clearly showed that Mexico was taking more than its treaty rights. See Resch, letter of transmittal.



Diversions from the Rio Grande Below El Paso. 1926. Records of the Bureau of Reclamation. Engineering and Research Center Project Reports, 1910-1955, Box 722, Mexican Canal Diversions in the Vicinity of El Paso. U.S. National Archives, Denver.

the Franklin Canal by 'running' most of the water around the International [diversion] Dam through the Acequia Madre head, then to the river through one of the two wasteways."[57] (See photos next page). Thus, in the fall of 1934, a low water year, badly needed water in the Rio Grande bypassed the intake of the Franklin Canal completely. This was not an anomaly, Resch argued, but rather such conditions and operations happened year after year, for the entire irrigation season. He argued that the omission of a headgate was responsible for the current situation of illegal diversions of river water to Mexico and the resulting and currently increasing difficulty of distributing water below the City of El Paso on the American side of the river. In compiling the records, he reported that the Acequia Madre diverted 57,241 acre-feet in 1916 and a similar amount in 1917, but diverted almost 90,000 acre-feet in 1919, and 81,000 acre-feet in 1920 and 1924. 1925 saw 94,000 acre-feet diverted to the Acequia Madre.[58] The unpredictability of the diversion made planning on the American side impossible. Furthermore, it was a well-known fact that in addition to excessive and unpredictable diversions in the Acequia Madre, Mexican farmers were also taking water directly out of the river below the Acequia Madre, a direct violation of the 1906 Treaty in which Mexico disclaimed all water below the Acequia Madre all the way to Fort Quitman.

Heightening the volatility of the situation and Mexico's excessive diversions was the fact that Mexico was openly entertaining new demands on the water supply from farmers in the lower end of the Juarez Valley *below* the Acequia Madre heading. A Mexican engineer was studying valley conditions, and a Mexican presidential candidate had overtly promised "to do everything possible to secure additional water from the Rio Grande for the lands in the vicinity of Guadalupe and San Ignacio, below Juarez."[59] The increased demand for water was the result of Mexico having expanded its irrigated acreage, an increase that Resch thought had begun around 1930. Initially, this increase in irrigated acreage in the lower end of the valley had coincided with – and was balanced out by – a decrease in irrigated acreage in the upper Juarez Valley due to waterlogged and alkaline conditions. But, like in the United States, Mexico had drained its waterlogged lands in recent years through the construction of at least 100 miles of drains, then gradually reclaimed those lands again for cultivation, creating an even greater draft on the Rio Grande. Resch estimated that there were 55,000 to 65,000 acres of land in the Juarez Valley that would come under irrigation again with the new drainage, clearly much higher than the original 25,000 acres anticipated by the 1906 treaty and used as the baseline for Mexico's 60,000 acre-foot allotment of Rio Grande water. Resch wasn't sure if the development of the lower part of the Juarez Valley for irrigation was officially sanctioned by the Mexican government, but he noted that there was a clear effort to pass Rio Grande water in excess of 60,000 acre-feet down to the lower valley. Once the river rectification project was complete, Mexico planned to conduct more infrastructure work on its canals so that the middle step of wasting back to the river would not have to occur.[60] This connection would allow water in the Acequia Madre to travel all the way down the valley to Guadalupe and San Ignacio.[61] Meanwhile, rectification would have important consequences on the United States' side of the river, as well.

Resch concluded his report by noting that "the only permanent solution" to the lack of American control of the

proper amount of water delivered to Mexico "is the construction of a diversion dam above the point where the Rio Grande becomes the International Boundary and an All American Canal built from the diversion dam along the American side of the river to the present Franklin Canal" so as to convey all of the water needed for the El Paso Valley directly to the Franklin Canal.[62] He thought the United States needed to step up and take responsibility for limiting Mexico's diversions under the 1906 treaty so that American Project farmers' crops would not fail. He also thought that Hudspeth District water deliveries needed to be protected against excess Mexican diversions going forward, since although Hudspeth had no Reclamation Project rights, the United States was certainly more invested in American farmers obtaining water than Mexican farmers.[63]

Other planned changes to the river also aimed to give the Bureau of Reclamation much better control over the water released from Elephant Butte Dam and deprive Mexico of any water other than its allotted 60,000 acre-feet. Furthermore, the construction of an All-American Canal upstream from the Mexican Acequia Madre diversion would add to the Bureau's control and result in a significant savings of water.[64] These changes – and others, including a wholesale rectification of the river channel that was discussed as early as 1926 but implemented in the 1935-1938 period (see Chapter 5 below) – would help to limit Mexico to its treaty rights and nothing more.[65]

Closing Out 1935

The shifting landscape and uncertain ground of 1935 led to significant events toward the end of the year. First, President Franklin Roosevelt issued a directive in September that there could be no new projects using Rio Grande waters unless the newly formed National Resources Committee provided an affirmative opinion. Roosevelt had created this New Deal federal agency and charged it with efficient regional development of natural resources; it was a quintessential part of Roosevelt's deep belief in the power of regional and resource planning.[66] Second, Texas filed a complaint against New Mexico in November in the United States Supreme Court alleging that New Mexico had violated terms of the 1929 Compact by permitting the construction of the El Vado Dam and development of the MRGCD, and arguing that the MRGCD had adversely affected flow into Elephant Butte Reservoir and negatively altered the salt content of the water therein.[67] Third, in December 1935, the Rio Grande Compact Commission acquiesced to basin-wide assistance from the National Resources Committee's Water Resources Group. At President Roosevelt's urging, the commission voted to permit this agency to facilitate a full investigation of the Rio Grande basin and its current patterns and data. Some of the findings in what became the multi-agency Rio Grande Joint Investigation Report would ultimately form the basis of the 1938 Rio Grande Compact.

Chapter 4: Arriving at an Equitable Apportionment: The 1938 Rio Grande Compact

Authorization and Scope of the Rio Grande Joint Investigation

Under the shadow of litigation in December 1935, the Compact Commission met to continue discussing apportionment and distribution of the Rio Grande. One of the focal points of this particular meeting was the presentation by Professors Frank Adams (University of California) and Harlan Barrows (University of Chicago), representing the National Resources Committee. This committee offered to design a comprehensive study of water use in the Rio Grande Basin to assist the states in dividing the waters of the river. While commissioners were slightly wary of handing over water investigations to a federal committee, they each recognized that a lack of data on water availability and water use in the basin still prevailed, particularly now that there were even more changes to the system with the construction of El Vado. They understood that arriving at an equitable apportionment depended upon closing any data gaps. In fact, Reclamation engineer and U.S. Compact representative S.O. Harper described the Compact Commission as having "reached a point where it was impossible to make any further progress without some workable plan for the collection and correlation of all pertinent data by a single agency."[1] Thus, an outline of this investigation's scope and findings – which became known as the Rio Grande Joint Investigation or "RGJI" – is critical to understanding the Compact, since the 1938 agreement was based on the data collected therein.

The professors began their presentation by posing several questions to the commission to guide the commissioners toward a resolution that would green-light and help guide the committee's study. Among the questions that Barrows and Adams felt the Commission should address in order to properly guide the study were: "What investigations are needed to determine the extent a) of the present use of water in the area, and b) of its use at the adoption of the compact?" And, "What, in the long run, will be your needs for water, not for irrigation supply, but for all other purposes, for city and town water supply, for industry, and the like? What are the prospects with respect to growth in population and the prospects for new and greater needs for water associated with that growth?"[2] Although there was some consensus among the commissioners regarding the benefits of laying the issues before "an unbiased tribunal,"[3] Barrows balked at this term, noting that the NRC's role would merely be that of an "eager assistant," and not that of a tribunal.[4] As discussions continued into the meeting's second day, New Mexico specified its desire to obtain data about the potential of augmenting the Rio Grande's flows, through storage, trans-mountain diversions, drainage, and the reduction of waste.[5] The other two states also commented on the study's content. Perhaps most significant at this stage were two points upon which the three states' representatives agreed: 1) that the investigation be purely fact-finding and non-binding on any one state;[6] and 2) that each state would seek funds to contribute funding for the work. After some negotiation over the resolution's wording, the commissioners resolved to move forward with the NRC's study and the RGJI was born. The expressed intent of the RGJI was to provide information that would permit the states

to make an equitable division of the waters of the Rio Grande without resorting to the courts.[7] It would be led by the two professors and Engineer in Charge Harlow Stafford, upon whose appointment all state representatives agreed.[8]

In the weeks following the commission meeting, the NRC began to facilitate the necessary studies. There were two critical components: compiling any relevant data that had previously been collected and obtaining any new data necessary to fill in the gaps. By the end of January 1936, the NRC had initiated communications with several federal agencies that would conduct different pieces of the new studies: the U.S. Geological Survey (USGS), the U.S. Bureau of Reclamation (Reclamation), and the U.S. Bureau of Agricultural Engineering (BAE). Each agency negotiated a memorandum of agreement with the NRC to conduct the research that fell within their respective areas of expertise. The investigations consisted of: water supply studies (of surface water, return flows, and, to a small extent, groundwater) to be conducted by the USGS; consumptive use studies of irrigated crops as well as natural vegetation, to be conducted by the BAE; studies of potential storage opportunities and stream augmentation, to be prosecuted by Reclamation; and water quality studies, also spearheaded by the USGS with help from the BAE. The NRC defined the underlying "problem" each of these studies would address in this way:

> The major problem of the Middle and Elephant Butte-Fort Quitman sections is the maintenance of an adequate water supply for irrigation of the lands of the Middle Rio Grande Conservancy District in the Middle section and of the Rio Grande Project and Hudspeth County Conservation and Reclamation district in the Elephant Butte-Fort Quitman section. With respect to the latter section, there is the further problem of maintaining satisfactory control of salinity in the irrigated areas.[9]

By compiling the results of each independent study as well as previously collected data, the NRC's RGJI intended to determine how best to protect existing rights (as they currently *existed in the law*)[10] as well as how to expand development within the limits of the resource.

Despite the definition of the overall "problem" to be solved by this investigation, constricted resources and limited funds meant that the studies the NRC commissioned focused on the resources under greatest threat and where the greatest controversies had occurred: those upstream of Elephant Butte. For instance, the USGS divided its study of water supply in the basin into surface and ground water investigations. The agency agreed to research stream and canal gaugings; measurements of return flows and waste; and underground water studies. They also worked with the BAE on water quality sampling. However, of the $109,000 budget outlined for the USGS's work, only $7000 of it was budgeted for *any* work downstream of Elephant Butte Reservoir.[11] Mostly, the agency reflected the Compact Commission's concern about the quality of water flowing *into* the reservoir as a measure of – in their minds – what was, in turn, being released downstream.[12] Furthermore, at a meeting of RGJI representatives on April 30 and May 1, 1936, consensus for "essential work" below Elephant Butte dam

10 As noted in Chapter 3, the Hudspeth Irrigation District was entitled only to unavoidable waste at the downstream extreme of the Rio Grande Project; that use and the limitations to which it was subject was to be protected.

11 "Rio Grande Joint Investigation: Stream and Canal Gagings, Measurements of Return Flow and Waste, and Underground Water Studies" (Water Resources Branch, U.S. Geological Survey, n.d.), Entry 454, Records Concerning Rio Grande Joint Investigation, Box 1, National Resources Committee - Rio Grande Investigation - Ground Water, U.S. National Archives, II.

12 "Regional Planning: Part VI--The Rio Grande Joint Investigation in the Upper Rio Grande Basin in Colorado, New Mexico, and Texas, 1936-1937," see Part V for a discussion of the relationship between salt content of water flowing into the reservoir and the salt content of the water being released.

provided only one line item for the Texas lands: "measurement of wastes below [the City of] El Paso only."[13] A memorandum of agreement between the USGS and the NRC reflected that this geographic and substantive breakdown of work was finally approved on February 28, 1936.[14] Thus the areas downstream of Elephant Butte, including those in Hudspeth County, saw little USGS study under the RGJI, demonstrated by the RGJI final report section related to the USGS's water quality and surface water studies, which stated that the "area of irrigated land in Hudspeth County…[was] not included in the Elephant Butte project or in the present investigation."[15]

The Bureau of Reclamation's work on storage opportunities also focused only on the upstream areas in Colorado and New Mexico above Elephant Butte. Reclamation divided its research into three sections: reservoirs, trans-mountain diversions, and power studies.[16] Reclamation's reservoir studies included examination of capacity, feasibility, and cost for several potential sites, including Wagon Wheel Gap, Vega Sylvester, and Conejos (a tributary to the Rio Grande) in Colorado; and the State-line, and Willow Creek (on the Chama) in New Mexico. (See map in Chapter 2.) Minimal study was needed on trans-mountain diversions, especially on the project known as the San Juan Diversion, considering that a fair amount of investigation had already transpired on that project. Finally, Reclamation's power studies constituted a minimal amount of work, with the estimate of work for this portion of the study totaling only $5,000.[17] In addition, the BAE would examine consumptive use in the basin from Colorado to Fort Quitman, examining evaporation, varying needs of different crops being cultivated such as alfalfa and cotton, and water consumed by natural vegetation. The agency examined and mapped vegetative cover and history of past water use, calculating water requirements along the way.[18]

Despite the Compact Commission's unanimous agreement on the joint need for more data collection at their meeting in December 1935, Texas immediately became the state which slowed things down. Not long after the Compact Commission agreed to work with the NRC, Texas's engineer adviser Raymond Hill wrote at length in late January 1936 to Texas colleague and Compact Commissioner Frank Clayton to express reservations about the RGJI's evolution and its focus. Texas's uncertainty and its consequent failure to allocate or commit funds was already jeopardizing the RGJI. Hill's six-page letter to Clayton is telling on several fronts related to Texas's position going into both the 1935 lawsuit against New Mexico as well as negotiations for a permanent compact. First, Hill felt that the price tag for various parts of the RGJI was far too high, and that "in-kind" contributions made by individual states through previously collected data as opposed to cash should be acceptable and would permit the federal investigation to continue. Second, Hill objected to the groundwater research being designed by USGS, arguing that the agency "should be limited in extent," and that "groundwater supplies along the Rio Grande *are of little importance in relation to the total supply*." He never contended that the Rio Grande Project owned groundwater rights, and he argued that groundwater should be studied only in the San Luis Valley because of the

Closed Basin and its potential to augment supplies, and even there only "if stations are favorable to the development of groundwater." [Emphasis added.] Instead, he wanted the USGS to focus on return flows and waste control. Finally, Hill complained generally about the social economic turn that he believed the study had taken by including a New Deal agency focused on rehousing the poor called the Resettlement Administration; Hill believed the agency's work was beyond the limits of what the commission had agreed to in December.[19] Commissioner Clayton concurred with Hill's assessment, and conveyed their concerns to the NRC just a few days later. Clayton told the NRC that Texas should bear a smaller cost for the study than the upstream states both because he believed Texas's own records were up to date and in good order, and because consequently, "little or no investigation will be necessary south of Elephant Butte dam." Clayton argued that "the acreage benefiting from the investigation is very much smaller in Texas than in either Colorado or New Mexico."[20] Finally, Clayton justified Texas's lower monetary contribution by pointing to the disproportionate amount of work to be done in Colorado's Closed Basin, the benefit of which was negligible to Texas.[21] When the engineers met informally in Santa Fe in early February 1936 to discuss the RGJI survey resources, Texas representatives voiced these concerns again to the group.[22] Nevertheless, the budget was set, and the hard work of collecting and analyzing data began. The group reiterated its demand that Texas contribute its monetary share of the work, a contribution that would take quite some time to obtain.[23]

Relationship of RGJI to Texas v. NM

As RGJI-affiliated studies progressed and evolved in 1936 and 1937, a picture of water use on the Rio Grande emerged in a new, more comprehensive way. As such, the RGJI became a tool not only to collect data to form the basis for a new, permanent compact, but also to make progress toward settlement of the ongoing lawsuit between Texas and New Mexico, which Texas had initiated in 1935 over what it claimed was a violation of the 1929 Compact by New Mexico through its development of the MRGCD and construction of El Vado Reservoir.

However, as the work progressed, more thorough studies into the basin's quality of water came to form a larger part of the RGJI than had originally been scoped.[24] In part, that was because Texas's Compact delegation and its litigation team recognized the difficulty of their state's case against New Mexico. Because it was proving hard to demonstrate that MRGCD construction was to blame for a decrease in water quantity into Elephant Butte Reservoir, Texas had begun to push the matter of declining water *quality* as a key argument in that lawsuit. The new focus on water quality may also have been related to salt incursion into the city of El Paso's municipal supplies that began in 1934. (This is discussed in detail in Chapter 5.) In September 1936, as Texas was preparing for upcoming hearings in front of

21 As survey details and costs were ironed out, the states' collective contributions were figured to be $55,000, or approximately $18,500 each. Texas's legislature was not scheduled to meet again until January 1937, and Governor John Allred had no authority to allocate funds without the legislature. Although Texas's late or potentially nonexistent contribution was controversial among the RGJI participants, the state did ultimately contribute its equal portion of the $55,000, in the amount of $18,333.33, once its legislature convened in early 1937. U.S. Supreme Court-appointed Special Master Charles Warren in the *Texas v. New Mexico* case, Hill explained the two "distinct divisions" of evidence that the state planned to pursue. The first was New Mexico's violation of the 1929 Compact, and especially the provision prohibiting New Mexico from allowing the water supply of Elephant Butte Reservoir to be "impaired." Hill interpreted this language to mean that no change could "reduce the value of the water supply."[25] Nevertheless, Hill anticipated that proving this point was going to be difficult for Texas, since accurate records were lacking. He even stated that "definite proof" of New Mexico's Compact violation would be "very difficult, if not impossible."[26] It would be very difficult to determine, for example, whether New Mexico had in fact increased its diversions, although Hill was convinced that New Mexico has seen an "increase in the amount of acreage served." As a result of these challenges in Texas's case, Hill had concluded that to prove New Mexico's Compact violation, Texas's second prong should focus on a *water quality* demand instead of water quantity, arguing that "there must be passed out of the Valley at least as much salt" as was brought *into* the valley. This second "division" of Texas's case would depend on a demand for what he called "equivalent service." He made the most succinct statement of this in a September 1936 letter to Clayton: "the lands in the *lower end of the El Paso Valley Division of the Rio Grande Project* are entitled to and should receive service equivalent to that of the lands in the Mesilla Valley. This has not been the case in the past and in order to accomplish this more reservoir water must be passed down the river for use on lands in the lower end of the Project, *regardless of the amount or quality of water which the Hudspeth District diverts into its canal*."[27] (Emphasis added.) Hill felt confident that Texas could show that more (not less) water was needed in the lower part of the Project lands "to give equivalent service and to maintain the salt balance" throughout the Rio Grande Project. However, it is important to note that neither Hill nor his contemporaries ever suggested that lands *below* the Project were entitled to this same service.[28] Ultimately, the takeaway from Hill's correspondence to Clayton was that Texas used the concept of water quality as a way to demand bigger releases from Elephant Butte to satisfy Texas's concerns over a potential decrease in *quantity*.[29]

Hill did recognize the challenging nature of the position he was recommending that Texas adopt, and correctly anticipated the substance of New Mexico's defense. Even after hearings in front of the Special Master had commenced, Hill told legal advisor Major Richard Burges that Texas would be hard pressed to prove that the MRGCD development had caused "any material continuing reduction in the *quantity* of water reaching Elephant Butte Reservoir," and that Texas "must rely largely on the fact that reduction in *quality* will necessitate the use of more water on the lands below Elephant Butte."[30] [Emphasis added.] Hill speculated that New Mexico's legal defense would focus on problems related to Project waste, illegal diversions to Mexico, and the delivery of water to Hudspeth, and would argue that without these problems, Project lands would have more water than they "could possibly use." Hill did not seem to have any ideas on how to refute these claims.[31]

To press its case, Texas focused on the quality of water being delivered to Project lands under the Riverside and Tornillo Canals in the El Paso Valley. Texas would somehow have to demonstrate that the construction of the MRGCD infrastructure (El Vado dam and drainage throughout that district's boundaries) had caused a lower

quality of water to be delivered to Elephant Butte, and consequently, to Project lands downstream, especially those in the El Paso Valley. In the months of correspondence regarding these studies, however, Hill never expressed concern over the quality of water being delivered to the Hudspeth District. In fact, Hill's concern was that the delivery of water to Hudspeth would be one of New Mexico's best arguments against Texas's position.[32]

In managing the case before him, Special Master Warren recognized the value of the investigative work being prosecuted by the RGJI to the issues being litigated in his court. Following many days of testimony in fall 1936, Hill characterized Warren as remaining dissatisfied with the "definiteness of proof" related to the effect of MRGCD on quality of water downstream on the EPCWID Project lands.[33] As a result, despite the fact that the official RGJI was due to conclude in June 1937, Warren requested that additional data be gathered on these issues. Consequently, attorneys for Texas, New Mexico, and the MRGCD signed a stipulation agreeing to continue parts of the general program of the RGJI. The stipulation (the content of which was facilitated by the Special Master) first required New Mexico to continue collecting data in the Middle Rio Grande Valley, and second, it demanded that Texas continue the program of measurements in the El Paso and Hudspeth Valleys, and either continue or institute quality of water studies at "all regular gauging stations between Elephant Butte and Fort Quitman and drain waters in the El Paso and Hudspeth County districts," into and during 1937.[34] The stipulation included both valleys (instead of only El Paso) since farmers in both areas did in fact receive water from Elephant Butte, and both therefore, would suffer from a quality impairment if one existed; however, without the data it would be impossible to know. Once the stipulation was executed, a new round of negotiations over cost responsibility and specific study tasks ensued before the continuing and new work began, since the majority of the RGJI work was complete and funding nearly depleted.

Texas found itself in a bit of a pickle with this stipulation. Having provided only lukewarm support for the RGJI in early 1936, the state now faced a dubious Special Master in a lawsuit which *it* had initiated. Texas knew it needed to gather data to prove its case, but again faced a funding problem. When the State of Texas failed to allocate funds for the work to which the parties had stipulated, Hill was left to seek other sources to foot the bill. Even Clayton expressed his concern early on about the costs,[35] but Hill plodded forward, recognizing that Texas's existing data was *not* enough to meet the demands of the stipulation and telling Project district colleagues that, "a rather comprehensive program of water analyses covering the area between Courchesne and Fort Quitman will be necessary."[36] In fact, Hill approached the Project districts – EBID and EPCWID – for a contribution to the study costs: "The State of Texas, which is in effect the two Districts…is obligated to determine with as great an accuracy as practicable the magnitude of all diversions from the Rio Grande below Courchesne [a measuring point near El Paso], all waste back to the river, and the discharge of all drains between El Paso and Fort Quitman."[37] Hill pleaded with the district managers to contribute $40,000 toward the study effort, arguing that, "it should be realized by each Board of Directors that the expense approximates 1% of the gross crop return, which is small insurance against a permanent reduction in production which is inevitable if irrigation developments upstream cannot be prevented."[38] Hill worked tirelessly to meet the demands of the stipulation by herding the different federal agencies and even the International Boundary Commission into agreeing to assist

with resources, asking the latter to install and operate new river stations between Courchesne and Fort Quitman to obtain the measurements required by the agreement.[39] But each agency had its own mission to consider as it offered assistance; none were obligated to do Texas's bidding.

By June 1937, unlikely partner New Mexico had stepped up. That state was as doubtful as the Special Master as to the effects of MRGCD's actions on water quality and wanted a full set of data for different reasons: to disprove Texas's claims. Additionally, MRGCD's manager H.C. Neuffer had spoken with McClure and expressed his district's interest in seeing the data, as well.[40] Finally, New Mexico expressed well-founded skepticism that Texas would itself be able to execute on the data gathering required by the stipulation.[41] By the end of the month, "New Mexico's general interest in this problem and particularly her interest in including Hudspeth County," State Engineer McClure said, was enough to convince the state to allocate $10,000 in order to obtain detailed data on the salt content "before the [Special Master] hearings start again next January [1938]."[42] Hill also convinced the Bureau of Reclamation to assist with the required stipulation measurements, with Reclamation in turn charging EBID through normal operation and maintenance fees.[43]

With the stipulated studies funded, Texas maintained that equivalent service must be provided only *on Project lands.* With the Bureau of Reclamation now at the helm of taking measurements, and in consideration of that agency's limited personnel, Hill maintained that it was necessary to restrict Hudspeth District measurements so that no more than two days a week would be devoted to that work; Hill was concerned about spending too much time on Hudspeth – what he deemed "data of secondary importance" – and expressed concern that too much time spent on Hudspeth would sacrifice the work he deemed to be of "primary importance."[44] Ultimately, the program would measure 11 wasteways and three drains in Hudspeth County.[45] As for any groundwater observations in Hudspeth, Hill recommended simply taking measurements at some of the existing wells a few times a year but noted that no major work was necessary to improve or add wells. As for salinity, sampling would continue at various points between San Marcial (above Elephant Butte Reservoir) and Fort Quitman.[46]

RGJI and the Rio Grande Compact

At the same time that New Mexico and Texas were determining the details of the stipulation studies, the NRC's role and mission in the RGJI was evolving. In March 1937, roughly a year after the studies had begun, Professor Barrows found support from the commission for an expanding role, and requested authorization from the

Compact Commission to create a special committee within the NRC to recommend a plan for a permanent Compact based on the findings of the RGJI.[47] Barrows also urged another extension of the temporary compact at the March meeting of the Compact Commission, since the NRC needed more time for the RGJI to be completed and to work out the details of a proposed compact based thereon. The commissioners agreed, and extended the temporary compact another six months to October 1, 1937.[48] The proposal to transition the NRC's study from merely providing data for the commission to providing recommendations and a proposal for the equitable apportionment of the Rio Grande was ultimately accepted by each state's delegation,[49] representing a dramatic change from the commission's early reluctance to permit such analysis.

Even as investigative work pursuant to the legal stipulation in *Texas v. New Mexico* continued, the RGJI study itself wrapped up, and the final report went into production over the summer of 1937. To determine next steps toward a permanent compact, the Compact Commission scheduled its next meeting for September 27 – October 1, 1937. The NRC provided Compact Commission members with some of the voluminous Joint Investigation report prior to the meeting, but with too little time for them to conduct a thorough review before convening. Nevertheless, the report's contents formed the very foundation of the meeting. At the meeting's opening, Commission Chair and U.S. Compact Commissioner S.O. Harper announced that the goal of the gathering was to review the RGJI's findings and to establish the basis for a permanent compact. When RGJI Engineer in Charge Harlow Stafford took the floor, the lengthy discussion began.

Mirroring the ongoing controversies between the states, the study had focused on key problem areas: potential storage in Colorado and at the Colorado-New Mexico state line; irrigated acreage and water quantity and quality in and downstream of the MRGCD; and drainage return on the Project lands in the El Paso Valley. Stafford explained that the results were reported in five sections. Part I, the General Report, provided an overview and conclusions of the entire investigation. Therein, the authors (several from each agency, plus Stafford, Barrows, and Adams) noted that the "prime purpose" of the RGJI was "to determine the basic facts needed in arriving at an accord" among the three states "on an allocation and use of Rio Grande waters in the *future development of the upper [Rio Grande] basin [in Colorado, New Mexico, and Texas].*"[50] [Emphasis added.] Part II was comprised of the findings from the USGS related to groundwater in the basin. Part III was the BAE's report on water utilization, and Part IV represented the report of the Bureau of Plant Industry related to water quality. Finally, Part V detailed the Bureau of Reclamation's results related to water storage and possible stream augmentation. Stafford reported to the commission on the report's findings, which are summarized below.[51]

Key Findings of the RGJI

Part 1 – or the "General Report" of the RGJI publication – provided a succinct yet detailed summary of each section of the study, and is useful for explaining the investigation's findings. First, the investigators explained their methods. In an effort to estimate supply for "the major units of the upper basin under given future conditions of irrigation development," they examined existing conditions, taking return flows into consideration due to their significant role in watering the basin.[52] The entire investigation covered 2,093,000 acres, on which they found an average of 3,860,000 acre-feet of water was consumed annually.[53] The report authors compiled all of the previously available data as well as the new data that was collected during the investigation and ran 11 different "combinations" – or what we might today call models – to determine how various scenarios of storage and draft on supplies would operate and function throughout the basin. They looked at storage in various potential facilities upstream from Elephant Butte, including Wagon Wheel Gap and Vega Sylvester, and evaluated how flows would compare at different gauging points along the river under each of those 11 scenarios.[54]

Their findings provided the Compact Commission with a basis for devising a permanent compact, and are therefore important to understand. First, study authors found that in a year of normal supply, an average surplus of 177,000 acre-feet existed in the upper basin, and reported that the average flow past Fort Quitman over the previous 13-year record was 211,000 acre-feet.[55] They explained that the study considered trans-mountain diversions from the upper San Juan River Basin and the "salvage of present wastes and losses" to be the only potential new sources of water in the Rio Grande Basin, the latter being consistent with and anticipatory of Reclamation's efforts to run the Project efficiently as well as with overall contemporary efforts toward conservation of resources.[56] Despite there being no groundwater data to speak of in the stretch between Elephant Butte and Fort Quitman, the General Report opined that groundwater use would not contribute extensively to the overall supply.

The report did make findings related to groundwater nevertheless, calling it "another source of water supply in the upper basin,"[57] and commenting that nowhere in the basin had this supply been yet "utilized to any appreciable extent as a primary or basic source of supply for irrigation." The authors continued: "there appears to be no immediate probability of extensive ground-water development as a basic supply."[58] Despite these comments, the authors recognized that the studies that formed the RGJI had not focused a great deal of attention on groundwater development, and where they did, their focus was on the area upstream from the Project in Colorado's San Luis Valley and New Mexico's Middle Valley sections. In fact, the report specifically called out that groundwater data for the downstream Rincon, Mesilla, and El Paso valleys "are very meager and no study of ground-water conditions in them was included in the Rio Grande joint investigation. These valleys comprise the Rio Grande Project, which is well provided with open drains that satisfactorily ground-water

levels at the depths below ground surface required to prevent waterlogging and seeping of the land."[59] In other words, the scientists' concerns in these lower valleys – when they expressed them at all –were not over whether groundwater could provide an additional source of water, but whether the drains were functioning to prevent seeped lands. As discussed in detail below in Chapter 5, the knowledge of groundwater's relationship to surface supplies in these lower valleys was still nascent and developing, and several additional studies completed in the years following the RGJI underscored how little scientists and water managers knew about these lower groundwater basins at the time of the RGJI or during negotiations of the Compact between 1935 and 1938. It is relevant to note as well that RGJI authors never state or suggest anywhere in the entire 600-page report that the Rio Grande Project had filed on or owned groundwater rights in these lower valleys.

In addition to examining supply, Part 1 of the RGJI also reviewed and quantified existing diversion requirements down to the lower end of the Project, detailing the storage capacity and stream depletion for each section of the river, starting upstream with the San Luis Valley and moving downstream to the Rio Grande Project. Hydrologists arrived at their numbers for the Elephant Butte to Fort Quitman section by examining the actual diversions and use of water for the years 1930-1936.[60] Then, the engineers modified the numbers to account for several factors: increased water to control salinity; decreased water to account for efficiencies that would be gained when the American diversion dam was in effect (particularly as it related to limiting Mexican diversion into Acequia Madre to the 60,000 acre-foot limit); and increased water when the Project's full expected irrigated acreage (155,000) was developed.[61] The report noted that the final figure did not include the Hudspeth district, since "its water supply is derived from and entirely dependent on residual flow drainage return, and waste from Rio Grande project."[62]

The investigation did also report its findings on municipal demands, but characterized them as "relatively minor."[63] The annual total depletion by cities in the study area excluding El Paso was estimated to be 21,000 acre-feet, assumed to be a draft on surface water, while El Paso was reported to take its 14,000 acre-feet for annual municipal and industrial demands from deep wells, assumed to be separate from surface supplies.[64] [See Chapter 5 below for a more detailed explanation of El Paso's water use and planned development.] Authors explained that "it is the use of water for irrigation and the disposition of it for that purpose which give rise to the problems of the basin with which this investigation is chiefly concerned."[65]

As for water quality, while the authors reported that generally speaking, the salt concentrations increased as the river made its way to the Gulf, they acknowledged that the data was "indefinite" at best, which was consistent with Special Master Warren's skepticism.[66] Although the report included tables showing the results

of sampling for dissolved solids gleaned from locations along the river, the accompanying narrative pointed out just how unclear the data was, and underscored Special Master Warren's skepticism about the effects of upstream development on downstream water quality. As it related to consumptive use, irrigation requirements, and concentration of the irrigation water and soil solution, Part 1 of the report stated: "Several equations have been developed to express the relationship between these elements, but as the *quantitative factors involved are yet somewhat indefinite*, it has been considered best, in this report, to *proceed more or less arbitrarily in assuming allowances to maintain the desired salt balance*."[67] [Emphasis added.] To arrive at a diversion demand and release from Elephant Butte Reservoir, the authors reported that they had arbitrarily provided a 60% increase in diversion requirement for the Rio Grande Project "and Mexican area" to account for salinity control in getting water to Tornillo, reporting that final number to be 773,000 acre-feet.[68] Further, they noted that in light of the indefinite numbers, and "after due consideration of the available information regarding adverse salinity conditions in the valley below El Paso, it was determined to assume the need for such additional water only in the area of the Rio Grande Project that lies under the Tornillo canal,"[69] excluding Hudspeth in those calculations.

Coming to Compact Terms

After Stafford reported on the substance of the report's findings at the September 1937 meeting, the RGJI committee (Stafford, Barrows, and Adams) had also planned to announce its recommendations for compact terms. But before they did, each state announced the terms that it believed were necessary for its own interests. Not surprisingly, each state differed over how to calculate delivery requirements and how to account for Project storage in Elephant Butte. Based on the history of the previous ten years, each state's stance during negotiations came as no surprise. Colorado was concerned about inefficient water use in the two downstream states and insisted that any permanent compact would need to "include the necessary regulation of these waters for the most efficient use of the same."[70] Colorado also insisted that it be permitted to develop the San Luis Valley, and Commissioner Hinderlider presented graphs containing data taken from the RGJI showing that construction of a reservoir with a storage capacity equal to the Wagon Wheel Gap Reservoir could be constructed without harming downstream supply.[71] New Mexico's presentation insisted on two key things among a longer list. First, it demanded that the Compact prohibit Colorado and Texas from interfering with New Mexico's right to the development, irrigation, and cultivation of the 123,000 acres in the MRGCD, and second, as a means toward compromise with Texas, New Mexico insisted that the commission fix a "definitive amount of water" to which the Rio Grande Project would be entitled,[72] but noted that deliberations with Texas could only move forward if excess Mexican diversions were curtailed, and that country's 60,000 acre-feet limit was enforced following construction of the All American Diversion Dam and Canal.[73] Finally, Texas came with its own position. First, it

insisted that New Mexico be limited to a maximum of water it could store in reservoirs above Elephant Butte, based on 30% of the amount stored at any given time in the reservoirs between San Marcial and Fort Quitman, which included Elephant Butte and the new authorized Caballo Reservoir, discussed below in Chapter 5. It also crafted a formula demanding that additional water be delivered for specific increases in dissolved solids.[74]

One of the most challenging areas for compromise came in trying to determine Rio Grande Project water needs. Colorado disputed the 773,000 acre-foot number in the RGJI report, and held fast to a maximum of 750,000 acre-feet release from Elephant Butte, demanding that its own accumulated debits for under-delivery at the Colorado/New Mexico state line be reduced when releases from Elephant Butte exceeded that amount.[75] By October, Texas had calculated that more than the 773,000 acre feet be considered normal release, determining that 800,000 acre-feet was the proper amount, a number that Texas eventually found difficult to justify. Nevertheless, that number was consistent with Texas's position that although the Rio Grande Project had been operated properly over the previous 20 years, its error has been in releasing too little water – "in recent years, especially."[76]

After each state presented its position, Professor Barrows provided a document to the Compact Commission that outlined nine suggestions from the RGJI Committee to serve as the basis of a new compact. The document recommended the following:

1. That all three states cooperate in funding and constructing the San Juan-Chama Diversion;
2. That Colorado and New Mexico agree to maintain a schedule of state line and Elephant Butte flows, respectively, and be permitted to construct storage and develop its irrigation at will within the limits of that obligation;
3. That Colorado be permitted to reduce the scheduled flow at the state line commensurate with the amount imported from the San Juan Basin;
4. That the states form a Compact Commission with appointees from the governor of each state and a federal representative appointed by the United States President;
5. That the Commission appoint a water supervisor to maintain records, conduct investigations, and serve as an adviser;
6. That the states share administration costs equitably;
7. That they revise compact terms after a short-term trial;
8. That they adopt a provision permitting temporary adjustments of the flow schedule when a surplus of water was expected; and
9. Finally, that the parties agree to arbitration for any disputes that arose.[77]

Following the presentation of these points, the Commission adjourned, with plans to meet again later in the fall.

77 "Proceedings of the Meeting of the Rio Grande Compact Commission Held in Santa Fe, New Mexico, September 27 to October 1, 1937," 47–48.

A great deal of negotiating took place in the ensuing weeks, particularly among the state's advisory engineers, also known as the Committee of Engineers, comprised of E. B. Debler for the United States, Royce J. Tipton for Colorado, John H. Bliss for New Mexico, and Raymond A. Hill for Texas. In fact, the engineering committee was charged with taking the RGJI recommendations and working with them to come up with a detailed set of terms for a permanent compact. Informal negotiations continued that fall through written correspondence, until the three state engineers held a meeting in late November in Santa Fe to further hammer out the details and try to smooth out remaining sticking points. New Mexico's Bliss told Hill that the water quality in Texas was influenced by "so many factors" that New Mexico refused to take responsibility for delivering to Texas "additional water for salinity control in case that quality should change adversely."[78] Colorado remained committed to ensuring present uses and was opposed to any state line delivery schedule that would restrict Colorado's uses prior to the construction of storage. New Mexico, too, was wary of a guaranteed delivery schedule into Elephant Butte because of the factors that remained out of their control. Texas took the opportunity during the November meeting to discuss the issue of salinity with New Mexico's Bliss. According to Hill:

> Bliss recognizes the validity of our position but does not know how to measure the effect upon the water supply produced by any irrigation development above Elephant Butte. I believe, however, that if allowance is made for change in quality at Lovatos [sic] and use-averages over a reasonable period of years, rather than for individual years, are used, Bliss will recommend that some allowance be made for change in quality of water.

Finally, Hill summarized the conversation between the commissioners related to Texas's position regarding the 800,000 acre-feet requirement. Hill showed the others "by different methods of calculation" how he had arrived at this figure in order that "equivalent service" be provided "to lands below El Paso, in the Rio Grande project, or to maintain a salt balance in the El Paso area." Although Hill recognized that the Project's recent releases had been closer to 730,000 acre-feet, making it "very difficult to substantiate the 800,000 acre-feet requirement, especially as we can look to some reduction in diversion, particularly on that to Mexico," he remained committed to it, when other solutions became untenable.[79] For example, at one point, engineers drafted and considered language that addressed the total salt burden by volume, limiting it at certain points along the river and calculating new water delivery formulas when there were increased salt loads.[80] Such specificity did not make the final cut of the proposed compact due to push back from New Mexico and Colorado who recognized their arbitrary nature, but Texas's Hill felt confident that Texas's "salt problem" would nevertheless be addressed in the final compact in some other form.[81]

At the end of December 1937, the Committee of Engineers met once more, this time in Los Angeles and subsequently submitted a report reflecting their consensus to the Rio Grande Compact Commission. The report summarized the discussions of the engineering advisors during their meetings in November and December 1937, meetings that focused on the discharge of the Rio Grande at the Texas-New Mexico state line, the delivery of water to Elephant Butte Reservoir, and the development of detailed schedules of water deliveries. While the engineers had not dealt with the relative rights of water users in the three states, they had worked under the

Compact Commission's guidance that current water uses (subject to the same limitations as noted above) were to be protected in the Compact.[82] The engineers used 10 years of data to establish water delivery schedules at various points along the river. They established one schedule for deliveries from the Conejos River (a Rio Grande tributary in Colorado) and one schedule for the Rio Grande above Del Norte, Colorado, which, added together, represented the total water that Colorado was obligated to deliver to the Colorado-New Mexico state line. They established a year-round schedule for water deliveries into Elephant Butte Reservoir as well as one for deliveries into Elephant Butte Reservoir in all months except July, August, and September. These Elephant Butte deliveries represented the water that New Mexico was obligated to deliver to San Marcial, a measuring point just above the reservoir, but the authors noted that this obligation would have to be adjusted as the amount of natural runoff changed and as diversions increased between the Lobatos gauge and Elephant Butte.[83] The report, having accepted Hill's arguments, stated that "normal release" from Elephant Butte should be an average of 800,000 acre-feet per year, adjusted as necessary for any new downstream reservoirs. The engineers defined the limits on water delivery debits for each state, making sure to state that accumulated water debits in any state could never exceed the amount of water in storage at one time in that state.[84] In years with "unusable spill" from Elephant Butte Reservoir, all Colorado and New Mexico accrued debits would be cancelled. Another limitation that the engineers imposed was that neither Colorado nor New Mexico could increase the amount of water stored in reservoirs built after 1929 whenever there was less than 400,000 acre-feet of stored Rio Grande Project water. In addition, if Colorado built irrigation works to deliver water from the Closed Basin in the San Luis Valley into the Rio Grande system, that water would be credited to Colorado.[85] If changes in diversion or loss to Mexico occurred and affected the normal release from Elephant Butte Reservoir, the engineers stipulated that the effects of this loss would be shared equally between Texas and New Mexico. The engineers concluded that "these schedules and provisions would permit the maximum practicable use of the waters of the Rio Grande."[86] They recommended that the Compact Commission consider and include their schedules, limits, and recommendations in the final Compact. Finally, and very important to their understanding of the river system's dynamic nature, the engineers recommended that "provision be made for review of these matters after five years and for adjustments within the intent of the Compact."[87]

In the two months that passed between sending the engineers' report to the Compact Commission and the engineers meeting for a third time in early March 1938, several important players opined on the engineers' recommendations. One notable complaint was registered by MRGCD's H.C. Neuffer, whose January 8, 1938 memorandum expressed vociferous dissatisfaction with the 800,000 acre-feet recommended by the engineers as the normal release for Elephant Butte. Neuffer, speaking for MRGCD, noted that the mean release from the reservoir for the years 1927 to 1936 was 781,000 acre-feet, including "excessive quantities of water delivered to Mexico, avoidable project wastes, and savings which can be made after the channel rectification is completed." Using data from the RGJI report for support, Neuffer urged the commissioners to reduce the 800,000 acre-feet of Elephant Butte release to only 700,000, a number that Neuffer believed to be a "liberal allowance."[88] Correspondence between the commissioners transpired over the next month regarding similar details from the

engineers' report.

The concerns of MRGCD water users were taken up by New Mexico's delegation to the Commission but caused further tension between New Mexico and Texas. In a letter dated January 25, 1938, New Mexico's Compact Commissioner Thomas McClure channeled many of Neuffer's complaints in a letter regarding several of the report's provisions. He claimed that the engineers' report was "too vague and indefinite" and that it did not sufficiently set up the data the committee used to "work out the relationship of the flow at various stations." He also disagreed with the manner in which the report fixed the basis for water supply to Texas – e.g. the 800,000 acre-feet – stating that he and "others in authority in New Mexico," believed the basis to be "so far out of reason that it could not be considered as a basis for negotiating." McClure claimed that the engineers took too much liberty in their report, compromised the basic data, and overstepped their authority and he suggested that the commissioners reconvene at their earliest convenience in order to "give the matter further study."[89] Texas Commissioner Clayton responded just a few days later, expressing adamant disagreement with McClure. Clayton opined that he and "those interested" in protecting Texas's water supply found within the report "no recommendations for the benefit of Texas than what she is plainly entitled to." Clayton conceded to using the engineers' December 27, 1937 report as the basis for further negotiations in the interest of "an amicable settlement" to the three states' common problems. Clayton conceded that New Mexico and Colorado likely had no intention nor desire to "further deplete the waters of the Rio Grande system," and so "the basis suggested in the report will do no more than preserve the status quo as far at the *water supply* is concerned, while, at the same time, permitting New Mexico and Colorado to proceed with certain desired development."[90] [Emphasis added.] As an aside, Clayton criticized New Mexico for giving MRGCD too much influence and losing sight of the fact that there was "a very extensive section of [New Mexico] lying below the Elephant Butte Dam," and that its large vested interests were "likewise entitled to representation and protection, along with the Middle Rio Grande Conservancy District."[91] MRGCD's Neuffer was vehemently opposed to any compact provision that would require a fixed amount of water to be delivered into Elephant Butte, and certainly did not approve of the 800,000 acre-foot figure in the engineers' recommendations. As Texas's Hill put it: New Mexico "relies more upon the judgment of [MRGCD] than that of his own deputy and…apparently forgets that the New Mexico boundary extends almost to El Paso." Hill observed that "the Middle Rio Grande Conservancy District considers that a proper Compact would provide no restrictions on their use of water and at the same time would limit the Rio Grande Project to perhaps 700,000 acre feet per year." Hill maintained that it was not advantageous for the committee of engineers to meet again to consider these objections.[92] Colorado agreed with Texas.[93] When the United States' S.O. Harper responded to all the correspondence, it was merely to announce that the Compact Commission should plan to meet again in early March 1938.

The Texas delegation was frustrated with New Mexico's general lack of adequate representation on behalf of EBID in the ongoing discussions of the Rio Grande Compact Commission. Hill believed that New Mexico State Engineer McClure had lost sight of that district's interests, and suggested that it was time that Texas "cease being

the direct representative of an irrigation district situated in New Mexico." Hill assumed that as long as Texas continued to "bear the burden of protecting the rights of all lands under the Rio Grande Project," New Mexico would continue to side with MRGCD. Hill believed that the commissioners ultimately would insist that the use of water below Elephant Butte Dam be reduced, even if this reduction would only benefit Colorado, and that if such an agreement were to come to pass, then Texas would be in an "untenable position." To emphasize the Project districts' needs, Hill proposed that EBID representatives begin to "sit in on all conferences of New Mexico interests to the end that the Elephant Butte District may be given the same consideration by New Mexico that the Middle Rio Grande Conservancy District is given." According to Hill, this would position EBID to "demand of McClure the schedule of deliveries into Elephant Butte Reservoir," that would protect the interests of EBID; and at the same time Texas would demand the same deliveries so as to protect the lands in Texas.[94]

It is important to briefly recognize the role that Mexican diversions played in these negotiations, as well, since the international nature of the river remained a significant consideration in its overall administration, and all parties recognized the illegal and excessive diversions being made in that country. Estimates for the amount of water diverted by Mexican users ranged as high as three times the amount of that country's treaty rights to 60,000 acre-feet. Using the 1928-1937 period, John Bliss recommended that a 150,000 acre-feet figure be used as the "Mexican takings" above the Tornillo gauging station for the era,[95] and that the figure be used as the basis for determining the amount of water to be saved and credited to the three states.[96]

The engineers met again from March 3-9, 1938 in Santa Fe to discuss these recent developments and concerns. Bliss, representing New Mexico, recommended that the "normal" Elephant Butte release be decreased from 800,000 to 775,000 acre-feet.[97] The ultimate number arrived at by the engineers was 790,000 acre-feet, a number they ultimately defined as "actual release."[98] Furthermore, the engineers noted that the effect of changes to salinity in the Elephant Butte supply since 1930 "was left for future adjustment."[99]

Following the engineers' final meeting in March, their committee sent a letter to the Compact Commissioners, explaining how they arrived at their suggestions for the final compact. This letter was, perhaps, in response to complaints following the first engineers' report which had resulted in suggestions that were not substantiated by detailed reasoning. In contrast to the simplicity of the engineers' first attempt at making recommendations, this letter provided much greater detail on how the engineers arrived at each of their conclusions. First the letter described that the engineers "avoided discussion of the relative rights of water users in the three states, and were guided throughout...by the general policy…that present users of water in each of the three states must be protected in the formulation of a Compact for administration of the Rio Grande above Fort Quitman." The letter noted that rather than dividing river use by state, the engineers divided the Rio Grande above Fort Quitman into three sections: the San Luis Valley, the Middle Rio Grande, and Rio Grande Basin below Elephant Butte.[100]

The letter continued on to describe how the engineers had arrived at their detailed scheduled deliveries at Lobatos station, explaining the relationship that existed between the combined inflow of major streams to the San Luis Valley and the outflow of the Rio Grande River at the Lobatos station. According to the engineers, development of storage reservoirs upstream from the Lobatos gauging station could potentially disrupt the

relationship, which prompted the engineers to prepare two separate schedules for the Conejos (tributary) and Rio Grande systems. The letter included a table that displayed the “Conejos Index Supply” and “Conejos River at Mouths” for the last 10 years. The letter also included another table which showed the quantity of thousands of acre feet of water in the “Rio Grande at Del Norte” and “Rio Grande at Lobatos less Conejos at Mouths.” Importantly, the engineers’ letter maintained that “the obligation of Colorado to deliver water in the Rio Grande at the Colorado-New Mexico State Line [sic] in each calendar year shall be 10,000 acre feet less than the sum of the quantities set forth in the above tabulations, except for such departures from normal deliveries.” The engineers found that three provisions existed which would allow for adjustments within their preferred system. The provisions included any change in locations of gauging stations, any new or increased depletion of natural runoff above gauging stations, and any trans-mountain diversions.[101]

Next, the engineers’ letter discussed scheduled deliveries into Elephant Butte Reservoir, detailing that the relationship between Rio Grande water above New Mexico’s agricultural areas and inflow to Elephant Butte Reservoir was erratic due to variations in the discharges. The engineers attempted to use a formula that would minimize the influence of tributary inflow and finding “a reasonable relationship between the discharges of Rio Grande at the Otowi Bridge and San Marcial gauging stations when the months of July, August, and September were excluded.” Therefore, the engineers inserted a table which displayed the “Otowi Index Supply” verses the “San Marcial Index Supply” in quantities of thousands of acre-feet, representing the head and lower end of the Middle Rio Grande valley, respectively. The engineers also outlined that the San Marcial supply comprised the recorded flow at the San Marcial gauging station during the calendar year, except for the months of July, August, and September, and concluded that the table outlining historic flows should be the basis of New Mexico’s obligatory deliveries to the San Marcial gauge. The engineers’ report outlined four provisions upon which adjustments would have to be made, including any change in gauging station locations, depletion after 1929 in New Mexico’s natural runoff at Otowi Bridge, depletion of runoff during July, August, and September between Otowi Bridge and San Marcial due to construction after 1937, and any trans-mountain diversions into the Rio Grande between Lobatos and San Marcial.[102]

Additionally, the committee of engineers recommended a provision that would prevent both Colorado and New Mexico from increasing the amount of storage water in reservoirs constructed after 1929 if storage in the Rio Grande Project fell to an amount less than 400,000 acre feet, and further recommended that should works be “constructed after 1937 for the purpose of delivering water into the Rio Grande from the Closed Basin in San Luis Valley, Colorado shall be credited with the amount of such water delivered, provided the proportion of sodium ions shall be less than 45% of the total positive ions in that water.” In recognition of the difficulty of securing reliable records for stream flow at San Marcial and other gauging stations, the engineers recommended that the Commission operate several gauging stations in cooperation with the appropriate federal agency.[103]

The engineers’ March report concluded with a summary: first, they requested the commissioners take into consideration the factors that had influenced their conclusions and recommended that provisions be reviewed again in five years. Importantly, the engineers suggested that “the normal release from Elephant Butte Reservoir be deemed to be an average of 790,000 acre feet per annum, adjusted for any gain or loss of usable water resulting from the operation of any reservoir below Elephant Butte.” Lastly, the engineers stated that “it is our opinion that the application of all of the recommendations and provisions set forth herein will be equitable to each State and will permit the maximum practicable use of the waters of the Rio Grande.” All four engineers

personally signed the letter, as did a representative from MRGCD, under a statement that merely stated "I Concur."[104] Although Texas had not been able to convince the other states of the need for an 800,000 acre-foot "normal release" from Elephant Butte Reservoir, the draft compact's 790,000, based on the engineers' report, was not far off, and the March engineers' report formed the basis for the compact that commission lawyers then drafted.

Once the draft was complete and signed by each state's commissioners, Clayton touched base confidentially with lower Rio Grande water users to let them know that, "Texas got everything in this compact that could reasonably be hoped for [but] I would not want this opinion voiced in the press, for the reason that it might defeat ratification in the two upper States."[105] He emphasized this point just a week later, again asking that his opinion remain quiet for fear that Colorado and New Mexico might "get the idea that water allotted to Texas by the Compact is more than sufficient to take care of the needs of the Rio Grande Project" and therefore not ratify the Compact in their respective legislatures. Clayton maintained that "as a matter of fact, while I feel that Texas will receive under the Compact all the water she can reasonably expect, the amount is not more than enough to take care of the Project's needs, without reference to the lands below the project line....My opinion is that if ratification fails, particularly through any fault of Texas, the projects sought by Colorado and New Mexico will probably be given favorable consideration by the federal agencies, and then Texas will then be in the position of having to resort to litigation."[106]

The Compact Ratified

From the engineers' negotiations, the 1938 Rio Grande Compact was drafted, and all three states' commissioners signed it in March, with all three states also ultimately ratifying it. In describing this achievement in narrative format, engineer Bliss provided a few important explanations. First, he explained that the Compact and division of the river's waters were based on two calculated schedules: one, to the Colorado-New Mexico state line, and the other to the San Marcial gauge at the head of Elephant Butte Reservoir. According to Bliss, the location for the second schedule was chosen because "the Elephant Butte Project must be operated as a unit."[107] He also noted that while each state recognized that importation from another basin would be the only way to augment supply, that credit water "particularly in the Middle Valley, is the saving effected by the reclamation and drainage of seeped and swampy lands which formerly consumed large quantities of water."[108] In other words, water saved through drainage or reduction of water-thirsty riparian vegetation would be credited to the state in which such efficiencies occurred. As for the Rio Grande Project, Bliss explained that it would "receive all the water she has received in the past prior to 1930 whenever it is required for her normal releases; she may make annual releases averaging 790,000 acre feet whenever her available supply is sufficient to do so."[109] New Mexico seemed satisfied, but the Compact pleased the other two states, as well. Clayton's comments make clear his belief that the volume of water to be considered "normal release" would be only enough for the Project lands – not for Hudspeth – and that Texas was more than satisfied with the Compact terms. As Texas's Clayton put it, the Compact "represented a fair and equitable settlement of the controversies that have raged almost continuously

for over forty years between the three states."[110] Clayton also stated that "We feel that we have secured in this compact exactly what we were entitled to and all that we could get, as a practical matter, as the result of litigation."[111]

As a result of the Compact's ratification by Congress in 1939, Special Master Warren dismissed the *Texas v. New Mexico* litigation, explaining that the "case presented…in the pending suit has therefore become moot; and the issues are, so long as the Compact remains in force and complied with, settled."[112] Warren's report left the two states to use the Compact and the Compact Commission to resolve any future disputes over the river. Meanwhile, the Hudspeth district, who was absent from providing input into the RGJI studies and Compact negotiations, would soon find itself fighting additional battles to protect any supplies.

Chapter 5: The Rio Grande Project and Other Development during Compact Negotiations and the Joint Investigation

It's tempting to view the Rio Grande Joint Investigation and Compact Commission negotiations in isolation, or as events occurring in a vacuum. However, as the first four chapters of this report show, the Rio Grande Basin had garnered a great deal of attention from the scientific and diplomatic communities over the decades leading up to the Compact, owing in part to the river's status as the third longest in the lower 48 states, its meandering course through significantly varied terrain, and its role as part of the international border with Mexico. Interest in the river was no less intense in the 1930s, 40s, and 50s than it had been in the preceding four decades.

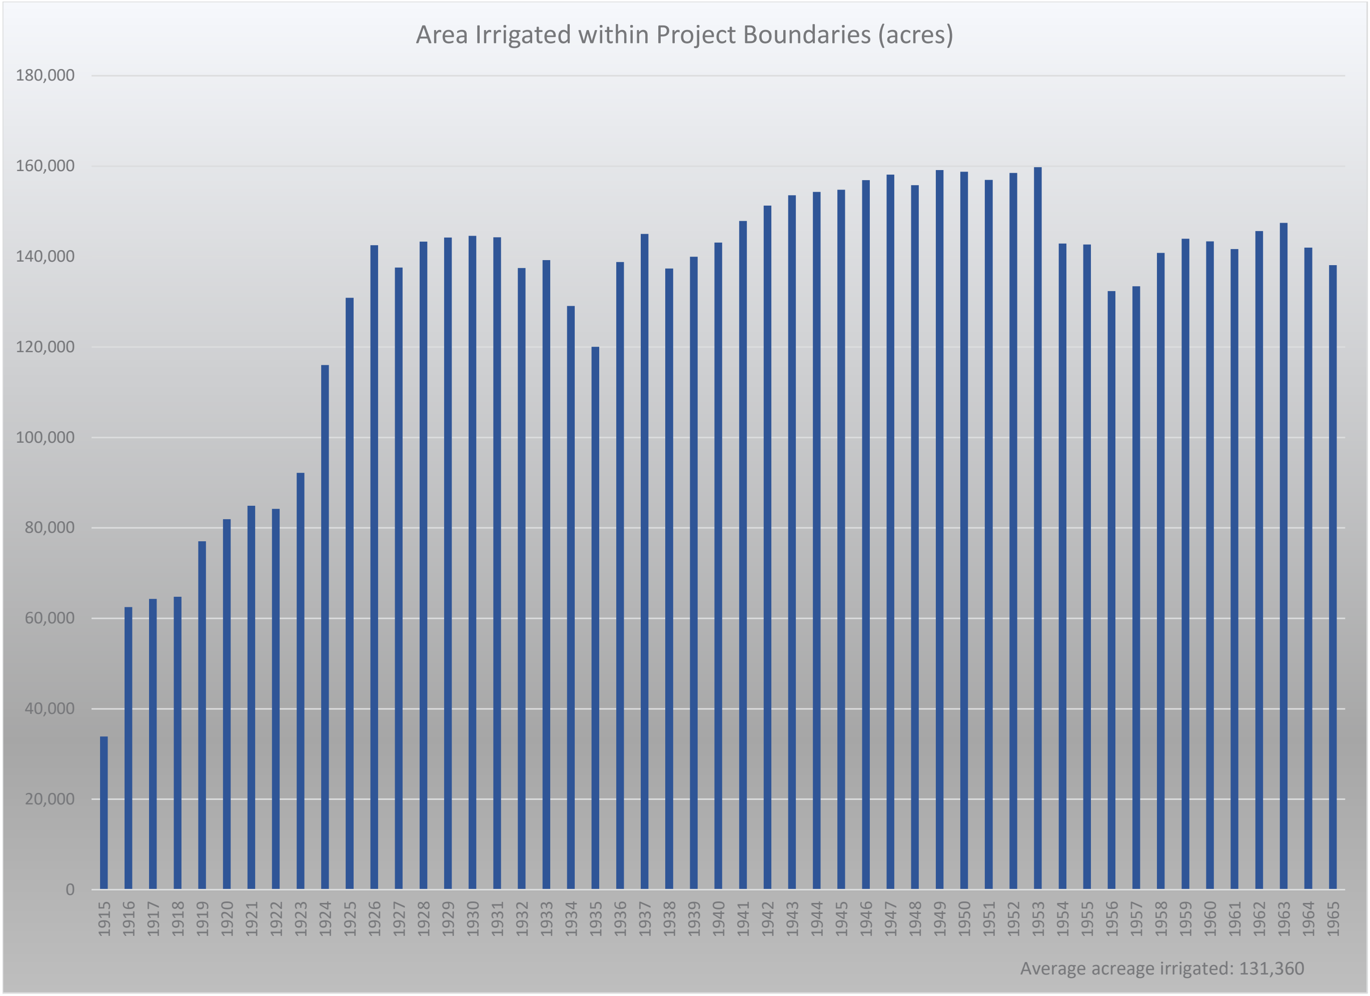
The river system changed dramatically during the years between the two compacts (1929-1938), and many studies were done as a result, as described in Chapter 4. But the Project evolved, too, both in terms of developed, irrigated acres as well as through changing water delivery infrastructure. Reclamation continually tweaked and refined the Project system to address efficiencies on the American side of the Project as well as to try to stop the continually increasing illegal Mexican diversions. The inter-compact years also witnessed localized interest in the administration of the Rio Grande, from investigations of municipal groundwater use in El Paso, to the signing of contracts between Project districts to provide more certainty and consistency on water delivery. Finally, these inter-compact years were important to international relations on the river, as well.

Then later, in the years following Compact ratification, water users and scientists undertook still additional investigations to find and locate supplementary sources of water, particularly for farmers in the Mesilla Valley. These detailed investigations, spanning the 1930s to the 1950s, demonstrated just how limited the understanding of groundwater/surface water relationships had been when the Project was authorized in the early 20th century, as well as when the Compact was signed in 1938. Although scientific knowledge of surface and groundwater connections was improving during Compact negotiations, the 1940s and 50s were a period of great growth in scientific understanding. Then, as the Upper Rio Grande Basin continued to evolve and operate under the 1938 Compact terms, severe drought struck the region beginning in 1946 and lasting into the 1950s, leading to groundwater exploration and discovery. Finally, other changes to the system eventually demanded that the 1938 Compact delivery schedules be slightly altered. This chapter will examine the developments of the 1930s that affected the basin's development and compact negotiations in less direct but still significant way, and will look at how the relationship between the Compact and scientific knowledge played out into the 1940s and 1950s when the region faced serious water shortages.

Inter-district Contracts

In the fall of 1937, just as Compact negotiations heated up, the two Project districts decided to negotiate an agreement regarding Project operation and maintenance costs as well as water allocation. The intent of the contract was to provide predictability and stability for the districts in the face of annual fluctuations that frequently occurred in irrigated acreage, project operation and maintenance costs, and water supply. During the first five years of the 1930s, the Depression had caused a significant decline in irrigated acreage in the Project, from 144,000 acres in 1930 to 120,000 in 1935. (See chart next page).

Such variations – split between the districts in myriad ways in any given year – could cause confusion and instability for things like operation and maintenance cost recovery as well as water delivery. The districts came



Irrigated Acreage Chart. Data from "Gross Crop Values - Rio Grande Project, New Mexico-Texas, Area Operated by Bureau of Reclamation" in Project History, Rio Grande Project, Vol. 54, Calendar Year 1965. New Mexico Office of the State Engineer Library.

to an agreement in September 1937 that was aimed at providing stability on these factors. They took their proposed contract to the Bureau of Reclamation and the Secretary of Interior for approval.

The inter-district contract was designed to address the annual variability in the cultivated lands of each district as well as the difficulty in knowing definitively the acreage to be irrigated each year. The contract outlined the two districts' basic understandings: there were 88,000 acres of irrigable land (57% of the Project total of 155,000) in the Elephant Butte district and 67,000 acres of irrigable land (43% of the Project total) in the El Paso district, and construction, operation, and maintenance charges for each district would remain constant every year based on these proportions, even if the irrigated acreage changed slightly in any given year. In fact, the contract provided that either district could increase its irrigated acreage by as much as 3% of its authorized irrigated acreage, or as much as 2,640 acres for Elephant Butte and 2,010 acres for EPCWID, while still maintaining constant operational charges. The small margin or buffer offered in the contract would also allow the districts to sustain minor losses in irrigated acreage "without disrupting the basic annual charges for construction repayment." EPCWID manager Roland Harwell assured Reclamation that despite small annual fluctuations, the accounting for each district would "remain in all respects unaltered, and unaffected by this agreement." Both districts hoped that the Secretary of the Interior would approve the contract. Harwell believed that, in this matter, the interest of the United States was the same as the interest of the districts.[1]

When the Bureau analyzed the contract in late October, however, Project Superintendent L.R. Fiock expressed his skepticism as to the contract's real intent. He believed instead that the districts' real goal with the contract was to have both districts "agree to and abide by the fixed percentage used in the allocation of construction costs of Project general features and in the allocation of water."[2] In other words, Fiock believed that the intent of the contract was to prevent one district from exceeding its allotted irrigable area to such an extent as to cause "a dispute or disturbance of balances between the two percentages agreed upon." He nevertheless believed the agreement prevented the districts from harming each other and thought the 3% margin reasonable. Fiock suggested that the districts add a clause limiting the amount of irrigation water applied to "suspended land under the water rental contracts," based on the amount of water in storage at Elephant Butte at the start of each irrigation season.[3]

Over the ensuing months – the same months during which the Compact Commission engineering advisors were hammering out the permanent Compact – the Secretary of the Interior and officials with the Bureau of Reclamation corresponded regarding the inter-district contract details. Reclamation Commissioner John Page (Elwood Mead's successor) wanted to ensure, for example, that the contract language did not obligate any district to pay a proportionate share of the cost for delivery systems that did not benefit their users; that the 57/43 cost split would only apply to common features of the Project system; and that, "in the event of a shortage of water for irrigation in any given year, the distribution of available supply in such year, shall so far as practicable, be made in the proportion of 67/155 (43%) thereof to the lands in the El Paso County Water Improvement District No. 1, and 88/155 (57%) to the lands within the Elephant Butte Irrigation District."[4] The United States and the districts made several alterations to the contract accordingly, specifically regarding the language surrounding the allocation of irrigated lands, irrigation water, and construction costs between the two districts. Reclamation officials were concerned that other contracts[5] being negotiated between the Bureau of Reclamation and EPCWID (these were related to repayment of drainage construction costs that were now necessary because of the Rio Grande Rectification project, discussed in the following section) would somehow be affected by the inter-district contract.[6] After addressing the concerns satisfactorily, the Reclamation Commissioner sent the revised contract to the Secretary of the Interior in November 1937, with no further objections.[7]

Finally, in February 1938, the presidents and secretaries of the two irrigation districts signed the revised contract.[8] The revised contract included language specifying that in the event of a water shortage the water

would be allocated in the proportion of 88/155 to the Elephant Butte District and 67/155 to the El Paso, or in a 57/43 percent split, respectively. The signed contract also stated that the agreement would only be effective "during the period when the proposed contracts under Public No. 249, Seventy-fifth Congress, 1st Session" between the United States and the two districts were in force, contracts that spelled out how development of power at Elephant Butte Dam would be accounted for financially with the districts.[9] If the Public 249 contracts were terminated, the inter-district contract would also be terminated. The final inter-district agreement also specified that the operation and maintenance costs of the Rio Grande Project works for 1938 and after would be distributed in the same manner and ratio as they were in 1937.[10] While conducted outside the official drafting of the Rio Grande Compact, the details of this inter-district contract played into the larger compact negotiations in important ways, cementing, in particular, the allocation of water based on these proportionate acreages.

Rio Grande Rectification Project and the Hudspeth District, 1935-1941

Significant physical changes to the river system were also transpiring during the 1930s. The Rio Grande Rectification Project, approved in 1933 by Mexico and the United States through signing of the 1933 Convention, changed the Rio Grande's channel downstream of El Paso. Plans for rectifying the river's course included straightening the Rio Grande's channel, reducing it from 155 miles in length to only 88,[11] and engineering it to flow on the south (rather than the north) side of San Elizario Island. The effect of the change would be to place the Tornillo Canal's heading, which fed Project lands in the lower El Paso Valley, entirely within the boundaries of the United States, thereby preventing Mexican users from having access to water in the riverbed below the Acequia Madre, the area Mexico had disclaimed all water by signing the 1906 Treaty. The 1933 Convention provided both for channel rectification as well as for the construction of Caballo Dam to better control the river's flow.[12] Caballo, situated 25 miles downstream from Elephant Butte in New Mexico, would be constructed between 1936 and 1938 and was planned to hold 100,000 acre-feet of water (it now holds 343,990) and control for flooding in the El Paso and Juarez Valleys.[13]

The U.S. Bureau of Reclamation worked with the International Boundary Commission to complete the project in response to long-standing disputes over the international boundary, the constant channel changes in the area below El Paso (where the river flattened out and was subject to damaging flood flows),[14] and as a means of preventing return flows from making their way back to the riverbed and becoming subject to illegal Mexican diversions. The project also included construction of the All-American Dam and Canal, designed to control the amount of 1906 treaty water diverted into Mexico's Acequia Madre at the old International Diversion Dam. The impacts of the project were significant, particularly in relation to Rio Grande Project operations at the lower end of the project.

In the years leading up to the rectification project, Tornillo District water users, located at the extreme southern end of EPCWID and the Rio Grande Project and who irrigated about 8,600 acres, had frequently and "emphatically" complained about the quality of their water supply. They were the last diversion on the Project and a large percentage of their supply came from drainage return water which ran high in salts. When the Tornillo District was initially incorporated into the Project in 1919, the early operating model aimed to address the water quality by mixing the drainage return water with stored water from Elephant Butte in a 50/50 ratio in order to achieve a tolerance limitation within which crops could survive. This practice of dilution had concerned Reclamation since the start, however, since although this mixture created usable water for the Tornillo users, it also created a total stream discharge that was more than twice the quantity necessary for Tornillo irrigation requirements. The practice resulted in excess water at the end of the system, which in turn created a water supply for the Hudspeth District, but Reclamation officials recognized, as noted above, that this supply would be unreliable as Project efficiencies changed as a result of the infrastructure modifications. As early as 1919, just as Tornillo was negotiating its inclusion in the Project and before Hudspeth's Warren Act contract was in place, Rio Grande Project manager L.W. Lawson (who would later be affiliated with the International Boundary Commission) wrote to the Tornillo District president to inform him that a continuation of the practice of getting useable water to the district by "wasting" such large amounts of reservoir water was "practically impossible," and that "it will be impossible for us to release the large quantity of water which has been placed at the disposal of the Tornillo irrigation district"[15] into the future, since it resulted in "reservoir stored water going to waste."[16] Project water released for dilution also created tension with upstream water users who complained that the Project was wasting water and engaging in inefficient practices.

Changes to the river as a result of rectification had the effect of changing the Tornillo District's water supply and therefore calling Hudspeth's source of supply into question.[17] According to Rio Grande Project Superintendent Fiock, the Bureau was most interested in "conservation of the project's water supply and the improvement of the quality of water delivered to the Tornillo District…" Rectification's effect in this sense was the achievement of a situation whereby "there should be some means for the separation or keeping segregated [Tornillo's] irrigation and drain water, or mixing it in desired proportions so that when water is wasted, it would be straight drain water, except as a portion of the drain water may be needed to make up the irrigation requirements, unless, of course, the upper valley irrigation water supply available at Fabens is in excess of the requirements."[18] While the changes described by Fiock could have been accomplished before rectification, changes to the river channel made the process of implementing this separation system much less costly, "greatly facilitat[ing] the practicability of accomplishing the separation of the irrigation and drain water."[19] This was a great benefit to Tornillo,[20] but when Reclamation and the International Boundary Commission completed the river channel rectification work in July 1938, the effect of this separation was a major change to the water made available to the Hudspeth District. Previously, Hudspeth had relied on the Project's operational model of releasing excess

Elephant Butte water to improve the quality of Tornillo users' supply in order to obtain its own irrigation supply. But the new modifications would jeopardize Hudspeth's access to that water. When Reclamation proposed new irrigation works in the lower end of the Project valley to better control and segregate the water supply following the completion of rectification and two short months after the signing of the Compact, the Hudspeth District recognized the uncertainty these changes posed to its supply. Consequently, Hudspeth management passed a resolution protesting the proposed infrastructure for fear they would deplete the Project water the district was accustomed to using. Both Project districts commented on Hudspeth's protest, with EPCWID writing extensively on the subject in May 1938. In sum, EPCWID disputed the idea that Hudspeth deserved either a quantity or quality of water equal to that of the Project's Tornillo District:

> Since the supply of water heretofore delivered to the Hudspeth District is stated to have been substantially sufficient for successful agricultural operations, the [Hudspeth] proposal, in simplest analysis, is that the Hudspeth District shall enjoy the same character of water right that the Tornillo District has. Further, since the Tornillo District [within EPCWID] unquestionably has a primary water right and is entitled to receive water both in quality and quantity at parity with other District lands, or in reasonable approximation thereto, the Hudspeth proposal, if put into effect, would automatically place that area on a basis of enjoying the same character of water right as the Project lands have. Or, failing in this latter respect; that the Tornillo District shall continue to be denied its rights by maintaining the present status. Of course, it will be readily noted that *nothing in the original contract between the Bureau of Reclamation and Hudspeth Conservation and Reclamation District, or any of the various supplementary contracts thereto, will support this claim.* The Hudspeth District is presumed to have the right to the use of such surplus waters as may exist at the terminus of the Tornillo main canal on payment for the same under rates mutually satisfactory to the various interests involved. *Beyond this, we can find nothing to indicate any responsibility of the project proper to supply water which may be regarded as necessary for the Hudspeth District lands.*"[21] [Emphasis added.]

EBID, having seen EPCWID's comments, wrote to the Project superintendent and informed him that EBID stood "with [EPCWID] to oppose the resolution directed to the Commissioner of the Reclamation by the Hudspeth County Conservation and Reclamation District No. 1."[22]

When Project Superintendent Fiock addressed the situation in a letter to the Commissioner of Reclamation, he noted that Tornillo users, "have been emphatically asserting their right to the same quality of water for irrigation as other portions of the Rio Grande Project, or at least the same quality of water as the upper divisions of the El Paso Valley." In Fiock's expert opinion, the Project was obligated to tightly control and regulate the water supply to meet the needs of those Project lands with "the least amount of waste and without any regard to the requirements of the Hudspeth District." Fiock recognized that operation of the Project with the least amount of waste would leave Hudspeth with only the "unavoidable and uncontrollable waste at the end of the project," which might be "wholly inadequate in quantity and too uncertain in time and regularity of availability to be relied upon for irrigation."[23] Nevertheless, Fiock, with compact negotiations still no doubt fresh in his mind,

noted that Hudspeth's rights were "legal" questions,[24] and concluded his letter by stating that, "it does not seem...that the [Hudspeth] District has any right or justification to stand in the way of improvements designed for the conservation or improvement of the project water supply, or any portion thereof."[25] Ultimately, Reclamation officials (beyond just Fiock) argued that the Project had no responsibility to supply any water to Hudspeth, and denied the district's protests.[26] In return, Hudspeth asked merely for assurance that its water supply would not be harmed, an assurance that it never received. Despite this clear denial of any right to either water quantity or water quality, things looked up for Hudspeth just a few years later, as described in a below section.

The Living Rio Grande Compact

To deal with these and other changes that would undoubtedly emerge in the basin, the Rio Grande Compact Commission under the 1938 Compact had recognized the need for a clear method of enforcing the agreement's terms while also providing for an adjustment phase in the immediate aftermath of the Compact's ratification. Negotiations for Compact administration mechanisms began immediately after the Compact was signed in March 1938. The commissioners recognized there should be what Texas Commissioner Frank Clayton called "an experimental stage" during the Compact's early administration, during which the three states could work out some of the granular details of Compact administration. Each commissioner would be paid a salary, and travel expenses for meetings and other requirements would be reimbursed. But for other details, Clayton noted that "the provisions of the permanent compact are highly technical and much more detailed than those of the temporary compact, and will correspondingly require more time and expense for their proper administration."[27]

In fact, that was true, particularly in the first few years. The Compact went into effect on May 1, 1939, with the Compact's schedule of deliveries becoming effective on January 1, 1940.[28] During 1939, the commission met four times to design and adopt rules for the Compact's administration, including the collection of data, staffing, how to handle new or increased depletions, and the future rotation of meeting locations.[29]

Things went fairly smoothly in the first few years, with water supply fluctuating as usual, and changes to the Project infrastructure continuing.[30] But in 1944, New Mexico initiated a more significant change to the terms of the Compact when the state made a formal request for the Commission to evaluate New Mexico's nine-month delivery schedule, which excluded the months of July, August, and September. New Mexico Commissioner and State Engineer Thomas McClure justified his request by noting that "substantial quantities of New Mexico credit

water have been delivered past San Marcial station from time to time during the July-September periods when no schedule accounting is made," and that New Mexico felt that a shift to a 12-month schedule would better serve the basic principles of the Rio Grande Compact.[31] Correspondence between the Rio Grande Compact Commissioners from July 1945 indicate that they all consented to the re-evaluation of New Mexico's delivery schedule, which occurred over the ensuing months.[32] With the data collected, the commissioners and the advising engineers worked out the details of New Mexico's new schedule in 1946. Texas's engineer Raymond Hill, with an established history of detailed Rio Grande analysis, reminded the commission that New Mexico's shift to an annual (12-month) schedule would have to comply with the limitations of the Compact's Article V which required that new stations and measurements result in by and large the same results "so far as the rights and obligations to deliver water are concerned, as would have existed if such substitution of stations and measurements had not been so made." In keeping with this requirement, New Mexico's future scheduled deliveries would be measured by something Hill called the Elephant Butte Effective Supply, defined as outflow plus or minus change in storage in Elephant Butte Reservoir, suggesting implicitly that the San Marcial gauge would be abandoned. Hill insisted that New Mexico's future deliveries (measured by the Elephant Butte Index) be equivalent to the quantity of water delivered to San Marcial during the three non-schedule months under the existing Compact. Finally, Hill maintained that adjustments would need to be made to "historical records to correct for such excess operating waste as did take place during July, August, and September," measured at San Marcial. Hill believed that the only adjustment possible that fell within the limits of Article V of the Compact was an allowance for operating water waste released from El Vado Reservoir during the three summer months of July, August, and September in excess of 25% of the total quantity released.[33]

By April 1947, the commission's engineering advisers had adopted a report recommending the replacement of the nine-month schedule with a 12-month schedule along the lines of Hill's recommendations. It had taken the advisers many months, but they ultimately found that the new schedule would reflect the old schedule "plus an evaluation of the deliveries of water through the middle valley to be expected during the three summer months which would result from the operation of the [MRGCD] under reasonable efficient conditions."[34] Ultimately, New Mexico's Bliss conferred with the state's attorney general, who believed that the change "would not be substantive in character," and that the Compact Commission could approve the change without legislative action.[35] In early 1948, the commission met in El Paso, and approved the change.[36]

The drought that began in the late 1940s, however, was another test of the Compact's provisions, and water users explored the potential of augmenting the supply with groundwater. That story and municipal use of groundwater will be discussed below.

Groundwater: Municipal Supplies

Yet another ongoing side story to the Rio Grande Compact narrative not previously discussed also began around 1935. In addition to Texas filing suit against New Mexico that year (Chapter 4), and the Compact Commission authorizing the Rio Grande Joint Investigation that year as well (Chapter 4), the role of groundwater began to loom large in discussions over water supply in the Upper Rio Grande Basin. Two events transpired to bring groundwater into Rio Grande discussions: first, the city of El Paso became desperate for a better and more plentiful municipal water supply beginning in 1934, and second, a severe drought hit the region hard starting in the late 1940s. The intensive nature of the investigations that were launched in 1935 outside of the RGJI to contend with these challenges point to the previously inadequate understanding of the relationship between surface and groundwater during the 1930s, as well as to the Upper Rio Grande Basin water users' intentions to explore groundwater as a potential supplement to augment the basin's supply.

El Paso's Municipal Water and the Rio Grande Project

By at least the turn of the 20th century, El Paso had come to depend on groundwater for its municipal water supply. By the mid-1930s, as the city grew, its pumpage had increased dramatically as well, and salt incursion into the supply was causing problems for the city by 1934.[37] In 1935, responding to requests from city of El Paso officials,[38] the USGS and the Texas Board of Water Engineers determined that an "intensive investigation of ground-water conditions at El Paso should be started as soon as possible."[39] The municipal El Paso Water Board concurred, and a combination of city, state, and federal dollars funded the USGS investigation beginning that summer.[40] The goals of the study were: to solve the problem of saltwater intrusion into the valley; to determine the quantity of water that could be pumped near and in El Paso, and; to determine the best locations to develop new wells.[41] The study was separate and apart from the other work being conducted throughout the basin for the RGJI, and its extensiveness underscored that neither scientists nor water users in the 1930s had a clear understanding of the resource; in fact, the USGS was performing the studies to determine whether groundwater uses in different parts of the El Paso area were a possible source of augmenting the current municipal supply, and what the effects would be of tapping into these groundwater sources. USGS began its work in July 1935.[42]

At the end of the following year, El Paso's Water Works Superintendent Ashley Classen became impatient for the study's results. In a letter to the USGS director, Classen explained that the city planned "a considerable program of new construction," all of which depended on the conclusions they hoped to see in the USGS report. For this reason, the city was very anxious to receive the findings so that it could plan for the coming year. Classen expressed his hope that it would be ready by January 1937 at the latest,[43] and USGS assured Classen that it would. One of the study's authors, A.N. Sayre, planned to travel to El Paso and go over the findings with

the El Paso Water Board at that time.[44] But in late January 1937, with El Paso's desperation increasing, Classen wrote again, explaining that it had become "imperative that we have two new well locations within the next thirty days." Classen exclaimed that El Paso was anticipating "a very acute shortage of water in our city during the coming summer" and would need to develop an additional water supply. The city's development depended entirely on the USGS survey's conclusions, and Classen emphasized how anxious the city was for this report so that they could select well sites, imploring the USGS to rush the report to completion.[45] A preview of the agency's conclusions and recommendations on the groundwater resources of the El Paso area suggested locations[46] where El Paso should drill its next wells, and recommendations on how to prevent further salt incursion.[47]

Although the USGS investigation into El Paso's groundwater supply was separate from the RGJI, the RGJI team was aware of El Paso's plight as well as of the city's dependence on groundwater supplies.[48] (See RGJI Report, (RIO30) p. 105) In fact, RGJI lead engineer Harlow Stafford requested data from Classen in January 1937, and Classen responded by sending El Paso's monthly pumping data from the city's wells for the five years between 1932 and 1936. The data showed that the city was fed by ten wells, each yielding 1,000 gallons of water per minute, averaging 3.5 million gallons per day during the winter and 7.5 million gallons per day during the summer. Classen informed Stafford about the USGS investigation and that the city was "contemplating the drilling and construction of 3 additional wells within the very near future," since the records clearly showed that "the static level of our ground water supply is slowly receding." With Classen's conclusion that "the pumpage in this area exceeds the recharge," he projected that if the groundwater supply recession continued for another 10 to 20 years, El Paso would need to seek a new water supply and warned that while the only other water supply available was the Rio Grande, he hoped that El Paso would not have resort to the river for many years, if at all.[49]

RGJI report writers, meanwhile, were wrapping up that investigation's report at the same time as the USGS report on El Paso groundwater was nearing completion. Although the RGJI mentioned the existence of municipal water uses in the basin, the authors more or less dismissed their significance to the overall depletions along the river in the upper basin, believing that some such uses affected the river while others did not. "The total use of water in the Upper Rio Grande Basin for purposes other than irrigation is but a small fraction of the irrigation use," they reported.[50] Nevertheless, they did display some understanding of the different underground basins' relationships to surface water, comparing Albuquerque's water use – a city with a population of 34,000 at the time the RGJI was written – with El Paso's (population 110,000). Albuquerque's "present use," they wrote, "is undoubtedly a draft, direct or indirect, on Rio Grande," but was nevertheless a modest 3,000 acre-feet total annually. In contrast, they believed that El Paso's 8,800 acre-feet annual supply of groundwater originated from precipitation falling on a large area east of the city, and they seem to have not considered El Paso's use a draft on

44 "Julian D. Sears, Acting Director, to Mr. Ashley G. Classen, Superintendent, City Water Works, El Paso, Texas," December 30, 1936, R.G. 57, Records of the Geological Survey, Entry 51, Director's Files, Central Classified Files, Box 461, 671 Texas (Ground Water), U.S. National Archives, II.

the Rio Grande.[51] In fact, the USGS still believed nearly a decade later in 1944 that groundwater dependence "for public supplies and industries" in the stretch of river between El Paso and Fort Quitman "relieves the demand on the flow of the Rio Grande."[52] In other words, scientists had a limited understanding of the relationship between groundwater and surface water and recognized that they did not have full scientific understanding related to every single underground basin along the Upper Rio Grande. Furthermore, contemporaries knew of El Paso's and other municipalities' dependence on groundwater, and also knew that these cities would grow. As such, it is not surprising to find a lack of evidence in the historic record indicating that Compact framers made any effort to preclude this resource's development.

In response to the USGS's El Paso groundwater findings, which provided detailed recommendations on which underground basins El Paso should pursue, the city began drilling new wells to gain a larger (and better quality) municipal water supply. When their efforts largely failed[53] (due to dry wells) El Paso was forced to approach the Bureau of Reclamation in the summer of 1940 to inquire about the possibility of acquiring Project water from the Rio Grande to supplement the city's supplies.[54] On June 8, 1940, W.E. Robertson, chairman of the Water Development Commission of the City of El Paso (successor to the El Paso Water Board) said that while the city's municipal water had mainly been pumped from underground wells for years, the water used had consistently exceeded the amount of recharge and had led to a higher risk of saltwater infiltration because of the lowered water table. To relieve El Paso's water woes, Robertson proposed to purchase land within the Rio Grande Project and thus acquire the associated water rights. The land purchased, then, would need to be taken out of cultivation. "There is no reliable, adequate, additional source," he pleaded, "except the waters of the Rio Grande."[55]

Reclamation officials did not immediately agree with El Paso's request. Although Reclamation Commissioner John Page passed the letter along to Superintendent Fiock with the hint that the proposal would "meet with [Page's] approval and co-operation,"[56] Fiock did not seem to share Page's feelings toward the proposal. "We believe the city showed poor taste in beginning its negotiations with an apparent endeavor to obtain water on more favorable conditions or charges than the project land," Fiock said, especially since El Paso "has been so dilatory through all the years of the project promotion and development, so far as we know never offering to bear any of the burden." Furthermore, Fiock felt that the city's claim of insufficient water was exaggerated for emphasis, and that some of the shortage might be explained by the city's delay in drilling a new well. He went on to say that it seemed that El Paso was faced more with a problem of water *quality* rather than quantity as the wells were depleted. He did acknowledge, however, that a supplemental supply from the river would extend the life of the city's underground supply by reducing the city's need to deplete it so rapidly, and despite apparent disagreement with some of the city's claims and the way they went about making their proposal, Fiock ultimately gave his

approval for the city to move forward with making arrangements, and directed city officials to seek approval from the Project irrigation districts.[57]

As negotiations proceeded with the Rio Grande Project, the City of El Paso relied upon the USGS studies to sustain its claim of a dire water supply situation in order to gain support for obtaining Project water. Doing so allowed the city to attempt to comply with the Act of February 25, 1920[58] requiring that "no such contract shall be entered into except upon a showing that there is no other practicable source of water supply for the purpose."[59] Having gained the support of the Bureau of Reclamation for the scheme, the city had negotiated all necessary contracts by early 1941. Key issues in these negotiations had included discussion over the city's repayment arrangements for Project water[60] and the amount of Project water to which the city would be limited.[61] El Paso felt that since it was purchasing land and taking it out of cultivation, it ought to be entitled to the same first-class water rights and the same deliveries as other qualified landowners. As such, El Paso disputed two particular clauses in the Reclamation contract. The first was one that allowed the Project Superintendent to decide not to supply the city with Project water in years when he might determine the delivery of water to the city to be "detrimental to the water service of the project or to the rights of any prior appropriator."[62] The second was the contract clause restricting the city to a maximum of 3.5 acre-feet/acre annually, arguing that no similar restriction was imposed upon any other landowner within the Project.[63] In the end, Reclamation removed the offending clause regarding "detriment" to other water users but retained the water volume limitations.[64]

The contract facilitating this purchase between Reclamation, the City of El Paso and EPCWID was executed March

7, 1941, stipulating that the city could obtain at most 2,000 acres of Project land in EPCWID and thereby obtain Project water rights for municipal use.[65] Both of the Project's irrigation districts approved the contract, which[66] provided that neither the United States nor EPCWID were liable for damages to the city if water quality was subpar or if water shortages occurred.[67]

As El Paso's municipal water shortage continued, the city proposed another analogous contract in late 1944, aiming to acquire the right to purchase up to 2000 acres of land in the Elephant Butte Irrigation District in New Mexico, and amending the 1941 contract such that the city's repayment arrangements would go to the districts and not to the United States.[68] All parties initially approved of this additional contract, but soon, New Mexico State Engineer and Compact Commissioner Thomas McClure intervened. In March 1945, McClure recognized a problem with the City of El Paso's plan. Writing to an El Paso city attorney, McClure explained that drying up land in New Mexico to benefit El Paso municipal uses was not in the best interests of his state; if El Paso needed water, he wrote, "they should dry up their own lands in Texas and not attempt to deprive New Mexico of her use of water." He added that if EBID was looking to abandon 6,000 acre-feet of water, New Mexico would surely find use for it "in New Mexico without selling it to Texas." He threatened that New Mexico's Interstate Stream Commission would not hesitate to use legal means to prevent this plan from moving forward.[69]

By 1949, El Paso's contract with EPCWID was in effect. But the one between the City of El Paso and EBID was in limbo. EBID water users had begun to feel the effects of the drought and were facing their own water shortages. As such, they sided with McClure, and expressed their own concerns over El Paso's efforts to sign contracts with EBID for Project water. EBID was further worried about El Paso's recently announced plan to construct a storage reservoir for city water, to be filled by using the city's allotted 3.5 acre-feet per acre of water for each acre it owned, plus any surplus water not needed by the Project, as determined periodically by the Project Manager.[70] EBID refused to approve the supplemental contract. Nevertheless, Reclamation's legal counsel eventually determined that EBID's approval was not necessary, and Project officials did not believe that the contract would be detrimental to EBID.[71] The waters to be contracted to El Paso consisted of water in several categories: 1. Flood waters accruing to the stream below Caballo Dam and below the last diversion point for EBID, after the needs of EPCWID and Hudspeth had been determined (Hudspeth did have an existing Warren Act contract that parties considered); 2) return flow waters during winter months, which were high in salinity and often unused by either Project or Hudspeth farmers because they needed dilution from storage water for irrigation use (and no waters were released during the winter months); and 3) "unavoidable waste" from sudden cold spells in the spring or from unexpected rainfall over irrigated areas during the summer months. A new gauging station was to be installed 16 miles above El Paso at the site of the proposed reservoir.[72]

As the drought worsened and there was no sign of it easing, El Paso launched additional groundwater studies with other partners, including the Army and the Air Force, both of which had bases in the region and also

demanded water supplies. The city's reliance on groundwater from the turn of the century well into mid-century and beyond and the state of Texas's and the Project's participation in helping the city solve its supply problems underscore the conclusion that the Compact did not intend to preclude the development of the resource.

Mexico Treaty Violations, Infrastructure Changes, and the Effect on Hudspeth

Meanwhile, the relationship between Hudspeth, the two Project districts, and Reclamation officials remained tenuous at best during the late 1930s and into the 1940s as the river came under Compact administration. Hudspeth had to advocate for itself for more than just a water supply during the late 1930s; it was also troubled by existing payment arrangements with the Project districts. EPCWID and EBID had, like other irrigation districts throughout the West, obtained new repayment contracts with the United States in the face of the Depression's severity and the aggressive payment schedule demanded by the original contracts. While it made a certain amount of sense to modify Hudspeth's contract at the same time as the Project districts and offer a similar level of relief, an August 1938 letter from Superintendent Fiock to the two Project districts explained why 1938 was an inopportune time for such a modification. These reasons included: "the pending litigation [between Texas and New Mexico] and present status of compact negotiations and such changes that may be brought about in the *kind of service* to be rendered to the Hudspeth District in the future on account of certain changes in the Project irrigation and drainage works."[73] [Emphasis added.] In other words, no guarantee could be made to Hudspeth, *especially* in the face of the recently signed compact that was awaiting ratification. Fiock reiterated the reasons to hold off on a new contract with Hudspeth as late as December 1939. In a letter to the Commissioner of the Bureau of Reclamation, Fiock noted that "a new contract should be entered into with the Hudspeth District as soon as the temporary and changing conditions now existing on the project, which may ultimately have some affect [sic] on the services which can be rendered to the Hudspeth District, have reached a permanent status."[74] Reclamation Commissioner John Page reiterated the sentiment in a letter to the secretary of interior: "It is proposed that a new permanent basic contract ... be entered into with the Hudspeth District at some time in the future, but until certain temporary and changing conditions on the Rio Grande project have been adjusted and become permanent, it will be necessary to continue making water rental contracts on an annual basis."[75] Following the signing of the Compact, Reclamation officials saw that the negotiation of a supplemental contract with Hudspeth, one that included reduced water charges commensurate with expected reductions in the district's water supply, would better reflect the water supply that the district would now receive.[76]

With the terms of the Compact settled, Hudspeth's rights to Rio Grande water were clear: they had none. Even so, the district's water delivery – jeopardized by the changes wrought through river rectification, and not protected by any terms of the Compact – was actually improved in the late 1930s and early 1940s thanks to Mexican users' defiance of the 1906 Treaty terms that continued even after rectification was complete. According to Acting Secretary of State Sumner Welles, immediately after the All-American Dam and Canal construction and rectification, Mexican users had – during 1939 alone – promptly constructed 14 diversions downstream of the Acequia Madre, taking an estimated 81,000 acre-feet more than the country's treaty rights.[77] While this in itself did not help Hudspeth, the U.S. response to these continued illegal diversions did.

When it came to illegal Mexican diversions, the United States remained deeply committed to protecting American water users, even those outside of the Rio Grande Project. In September 1940, for example, Reclamation's Chief Engineer S.O. Harper wrote to Superintendent Fiock and noted that recent Reclamation investigations had investigated ways of "eliminating diversions from the Rio Grande by Mexican interests below the All-American Dam and above Fort Quitman."[78] However, Harper also explained that "while the [Reclamation] Commissioner has mentioned the Hudspeth and other territory below the Rio Grande Project [in connection with proposed infrastructure changes], *it is understood that this reference was not intended to be a suggestion of providing a firm water supply to any areas below the Rio Grande Project, but on the contrary to insure that surplus waters which could be made available to these areas would not be taken by Mexican interests to the injury of possible United States users.*"[79] [Emphasis added.] Regarding lands below the Rio Grande Project boundaries, Fiock responded: "these lands below the project are, of course, as viewed by the Bureau and the Project Districts, *not considered as having any primary right in water from the project source of supply, but can be considered as entitled to all of the drainage and return flow and unavoidable project operating waste which may reach the lower end of the project, and thereafter be unavailable for project uses*."[80] [Emphasis added.] He continued in the same letter to state that "as pointed out above, it would appear that the Hudspeth District *is entitled to and can rely upon only the recovery of the drain discharge and operating waste from the lower end of the project for its normal supply*."[81] [Emphasis added.] To emphasize his point, Fiock enumerated the only circumstances under which excess water might flow to Hudspeth: "miscalculation in making reservoir releases to meet project requirements, unanticipated operating waste from upper divisions of the project above El Paso, slacking off of irrigation when rains occur on the project, or flood water originating from tributary arroyos below Caballo Reservoir."[82] Despite these caveats, the United States' commitment to American farmers (versus those in Mexico) led Harper to recommend that Reclamation investigate the excess Mexican water diversion problem in two phases: water supply for Rio Grande Project, and water supply for everything else below the Mexican Canal,

including Hudspeth.[83]

Harper explored several solutions for the first problem: reduce diversions into the Acequia Madre to compensate for illegal diversions downstream; enlarge the Project's Franklin Canal (located upstream of the Acequia Madre) to take more water; or provide a new feeder from the Franklin Canal to the Riverside heading to prevent return flows from returning to the river bed. Regarding water supply below the Project in Hudspeth County, Harper pointed out the following:

> The Tornillo unit [of the Rio Grande Project] is, first of all, entitled to a water supply suitable for satisfactory production of crops, but it *cannot be said* that the unit is entitled to water of the same quality as is delivered to the upper end of the El Paso Valley. Deliveries of water to this unit must be a compromise between an effort to deliver waters of the El Paso quality and the avoidance of undue waste of project water whether from operating waste or rejection of drain waters....Subject to providing the Tornillo unit with a suitable water supply, without unreasonable waste, every effort should be made to provide the Hudspeth District with the best supply that can be provided to the District out of the project waste and return flow ***net usable*** within the project...it seems advisable that the matter be covered by a separate report devoted solely to the plan for providing the Tornillo Unit with its water supply and general plans and estimates of providing the Hudspeth District with the best water that can be furnished.[84] [Emphasis added.]

By October 1941, Reclamation had instigated several infrastructure changes to assist with the problem of downstream delivery by circumventing return of drainage water to the riverbed and preventing Mexican diversions.

As noted above, earlier changes to the infrastructure had initiated a new era of water supply for Hudspeth in which its delivery quantity decreased by 30% in 1941 from the average supply of the previous five years.[85] However, the district seemed to survive these water supply reductions by making use of Tornillo Drain water at first, and, in 1941, taking advantage of the installation of few new feeder canals designed to divert Fabens drain waters straight to Hudspeth so that the district would not have to rely strictly on Tornillo Drain water, which had much higher dissolved solids.[86] Thus, in the face of changes to the Rio Grande system driven by the conservation of Rio Grande Project water and the reduction of illegal Mexican diversions, Hudspeth ultimately was able to take advantage of the U.S. Bureau of Reclamation's mission to make as much water available to American users as possible, even though it was widely acknowledged that the district itself had no legal right to Project water.[87]

83 It is important to note here that these comments were made two years after the Compact was signed. One would expect that Hudspeth's rights in this situation would have been more certain had the compact framers intended to include a supply of water for Hudspeth.

With the Compact signed and new infrastructure in place, the Bureau of Reclamation revisited the old issue of a base Hudspeth contract again in late 1943. In these negotiations, Reclamation recognized the instability of the Hudspeth water supply, and Reclamation's continuing efforts to eliminate as much Project waste as possible. "It is not yet believed," wrote Fiock,

> that it can be considered that the type or extent of service furnished to the District from the project can yet be considered as stabilized. Additional facilities are required for the District's salvaging of project waste and drain return flow water...*There is also the matter of the character and extent of service rendered by the project to the District, which cannot always be determined in advance*. *Charges should be somewhat in proportion to the amount and quality of water received by the District, character of service, and area irrigated or in cultivation, all of which can be, and are, variable from year to year.* In years of threatened or actual water shortage the service rendered to the District not only may be, but is, curtailed in greater proportion than the curtailment of service on the project, and depending upon the acuteness of the shortage, *may even result in a very limited service to the District, if any*.[88] [Emphasis added.]

Just a few months later in winter 1944, Fiock again offered his assessment of the Hudspeth supply situation in writing: "Until a thorough study and report can be made on the water supply available for the Hudspeth District, a new contract can be discussed only in a preliminary manner as the provisions of a new contract must naturally be predicated upon the water supply available for the District."[89] In March 1944, key Reclamation employees nevertheless met to discuss a new contract for Hudspeth, and District Counsel Spencer Baird drafted a document based on the consensus that emerged from that meeting. Baird opined that neither the uncertainty of supply nor the change in service should preclude a new Hudspeth agreement, since there had "never been complete satisfaction" with the original draft, and the annual negotiations were "cumbersome."[90] With the draft contract, the Bureau began negotiations with EPCWID and subsequently, the Hudspeth District, over specific contract terms.[91] Parties signed a final contract in 1945, a document that specified – in the event there was any doubt whatever – that "the right to use water hereafter is inferior to that of lands in the Project, and the District also agrees that its right to use any or all waters of the Rio Grande shall be subordinate to the use of such waters by the Project."[92] The contract also specified that the United States could not be held liable for any "insufficiency

of water" to Hudspeth lands.[93] In other words, Hudspeth's subservient status was reiterated in this permanent contract.

Drought: The Role of Groundwater for Irrigation

As referenced above, the Upper Rio Grande Basin and the entire Southwest region was hit by a serious drought that began in 1946, accelerated in the winter of 1946-1947, and lasted well into the 1950s. Water users soon recognized the severity of the situation and wondered how they would obtain enough water for their crops. While the Compact had anticipated years of water shortage, the document did not have any insights into how groundwater could be used in such severe situations. Without any official guidance on how to supplement Rio Grande water supplies when supplies throughout the entire upper basin ran low, the districts sought new investigations. The 1935-36 (and ongoing) El Paso groundwater study offered inspiration.

In 1946, EBID followed the City of El Paso's lead and requested that the USGS study the groundwater supply in the Rincon and Mesilla Valleys.[94] Anticipation of continued drought was the driving force behind the study, demonstrated by storage levels as low as 317,000 acre-feet in Elephant Butte in August 1947. With another month of irrigation remaining in the season, water users' concerns about supplies for the following season were heightened, and they hoped that groundwater might supplement their surface supplies. To answer the district's questions, the USGS's Clyde Conover conducted a series of investigations in EBID between 1946 and 1947.[95]

Following a year of study, Conover issued a preliminary memorandum at the conclusion of studies. In it, he remarked that the primary objective of his research was to investigate groundwater, "mainly from the standpoint of productiveness of wells and the effect of pumping upon the surface-water supply in the rivers and drains."[96] Conover had examined "the quantities involved in the present irrigation with surface water exclusively" in order to fully understand the effects of groundwater pumping in the Mesilla and Rincon Valleys.[97] In his findings, Conover made several important points that affected future water use in the region. First, he recognized that more water was applied to crops than they consumed and asserted that the amount of water applied to the land in past years was "doubtless more than actually necessary, even though irrigation of crops requires an excess of water applied."[98] Second, Conover described the connections between surface and groundwater, noting that any surface water released from Caballo Dam that was not lost by transportation or evaporation, seeped underground "from the canals and irrigated lands to return to the river as drain flow."[99] The over-irrigation of Project lands and the relationship between surface and groundwater in irrigation systems that Conover elucidated would play important roles in future water negotiations.

As far as groundwater use was concerned, Conover remarked that of the many operational wells that had existed in the Mesilla Valley in the early 1900s, "very few" of these remained in operation.[100] Most of them had been

abandoned "after a water supply was assured by Elephant Butte Dam."[101] However, Conover reported that in recent months, "a few irrigation wells" had been drilled due to the "contemplated shortages of water in 1948," although none of them had pumps installed at the time he wrote this memo.[102] Whether or not these wells – when engaged – would have a long-term effect on surface supplies, Conover concluded pumping would lower the water table, "at first in the vicinity of the well," but as time went on, "at greater and greater distances from the well," explaining that "all water pumped from wells" was "balanced by a loss of water from somewhere else in the ground-water system, either from the amount stored underground, from the amount seeping out of the aquifer, or, less commonly in arid countries, from the amount of surface water that the system is unable to absorb (rejects) because the aquifer is overfull under non-pumping conditions."[103] In other words, Conover concluded that pumping groundwater would only provide a small amount of net additional water to the Project as a whole, with water being diverted "to the pumps that would otherwise be available as surface supply lower down the valley."[104]

Despite these conclusions, however, Conover seemed to advocate for pumping as a short-term solution to the drought issue, a conclusion with which Reclamation agreed. Conover recognized that pumping would have the effect of drying out the drains of return flow, but also found that less waste (through transportation and evaporation) would be realized by pumping than through surface deliveries, at least a 10% savings, which was not insignificant during drought years.[105] In fact, Conover also concluded that *in years where surface water levels were only at 50% of the average supply*, he believed it would "*be necessary to pump some ground water*."[106] [Emphasis added.] Assuming that EPCWID also engaged in pumping for irrigation, he explained, such an effort would "save some of the water which would otherwise drain from the land, thus saving more water for the Project."[107] Conover recognized that the "pumping of wells would diminish the drain flow," which would "necessitate a corresponding decrease in the allowable diversions for the Elephant Butte Irrigation District"[108] but this did not dissuade him from his recommendation that pumping serve as a short-term drought solution.

In September 1947, Conover's USGS colleague Charles V. Theis sent a copy of Conover's preliminary findings to A.N. Sayre, the geologist in charge of the USGS groundwater division in Washington, D.C. This was the same man who had studied the City of El Paso's municipal groundwater use in the 1930s and early 1940s. Theis explained to Sayre that it was immediately necessary to release Conover's preliminary findings so that New Mexico's state engineer and EBID could "establish a policy" with regard to pumping, before "the situation gets out of hand."[109] With Sayre's approval, the USGS complied and sent the preliminary findings to the Project with a cautionary note explaining that detailed findings might differ in later reports. New Mexico State Engineer John Bliss also received a copy of the findings in October 1947.[110]

Despite the USGS's cautionary note, the Bureau of Reclamation took on the burden of working with Project

Sayre, Geologist in Charge, Division of Groundwater," September 10, 1947, R.G. 57, Records of the Geological Survey, Entry 575, Ground Water Branch, Administrative Correspondence, 1944-1954, Box 33, New Mexico, Albuquerque 1947, U.S. National Archives, II.
110 "Chas. V. Theis, District Geologist, to Mr. John H. Bliss, State Engineer of New Mexico," October 23, 1947, R.G. 57, Records of the Geological Survey, Entry 575, Ground Water Branch, Administrative Correspondence, 1944-1954, Box 33, New Mexico, Albuquerque 1947, U.S. National Archives, II.

farmers during times of shortage, encouraging them to be thrifty in their surface water applications but also to pump as a way to supplement limited surface supplies. During the 1947 irrigation season, Reclamation provided a packet for Project land owners, farmers, and irrigation districts called "Conservation in the Use of Irrigation Water: Principles and Practices to be Observed and Followed in the Control, Distribution, and Use of the Irrigation Water Supply for its Conservation and Maximum Production Results." One section of this packet, "Explanation of Principles for Conservation in the Use of Irrigation Water," explained to farmers the connection between irrigation, groundwater, and drainage, and warned farmers not to over irrigate, as "a limited portion of the water applied to the land must percolate on through the soil and by eventually making its way to the drains, provides the circulation needed to prevent the accumulation of alkali salts on the surface." The packet continued, "if excess water reaches the ground water table faster than it can escape to the drains, the water table rises resulting in seepage and alkali surface conditions."[111] Three years later, as the drought continued and conservation proved inadequate for its severity, Reclamation reported that if drought conditions continued, "pumping appears to be the most feasible for a short time" as a remedy.[112]

As the drought continued and Reclamation reduced annual per-acre water allotments from storage water, Reclamation tracked well data and encouraged farmers to continue the practice of supplemental pumping. Between 1951 and 1955, dwindling storage supplies in Elephant Butte led Reclamation to declare annual allotments ranging from just a few inches per acre to 2.5 acre-feet per acre so that all Project lands would receive an equal amount, but well below the 3.1 acre-feet needed by farmers for a successful crop. In 1951, the Rio Grande Project Manager told water users who were able to supply their water needs via pumping to arrange transfer of part of their unused allotment to those who needed more water.[113] Many of these users clearly took his advice to heart. The following year, in 1952, Reclamation reported that "1952 proved to be an excellent crop year for irrigation farmers" on the Ysleta branch (in EPCWID), because although storage was at a mere 10% of normal at the season's beginning, farmers had installed 220 wells during the 1950 and 1951 seasons, "which provided the necessary early water."[114] In 1955, the most severe season to date, the Project operated on a fluctuating allotment basis of five inches, but farmers supplemented their supply with 1650 wells, and the Bureau encouraged them to continue doing so.[115] Pumping was a way that the Bureau urged the farmers with wells to "help their neighbors" who were unable to dig wells.[116] By this time, with the drought extending to years, Conover's connections between ground and surface water and his encouragement to limit the amount of pumping seemed long forgotten and there was nothing to limit the use of the water of the Rio Grande that lay beneath the surface. But the appointment of Steve Reynolds to State Engineer in 1955 – a post he would hold for more than 30 years – altered the groundwater system in New Mexico with his focus on groundwater basin declarations and regulations.

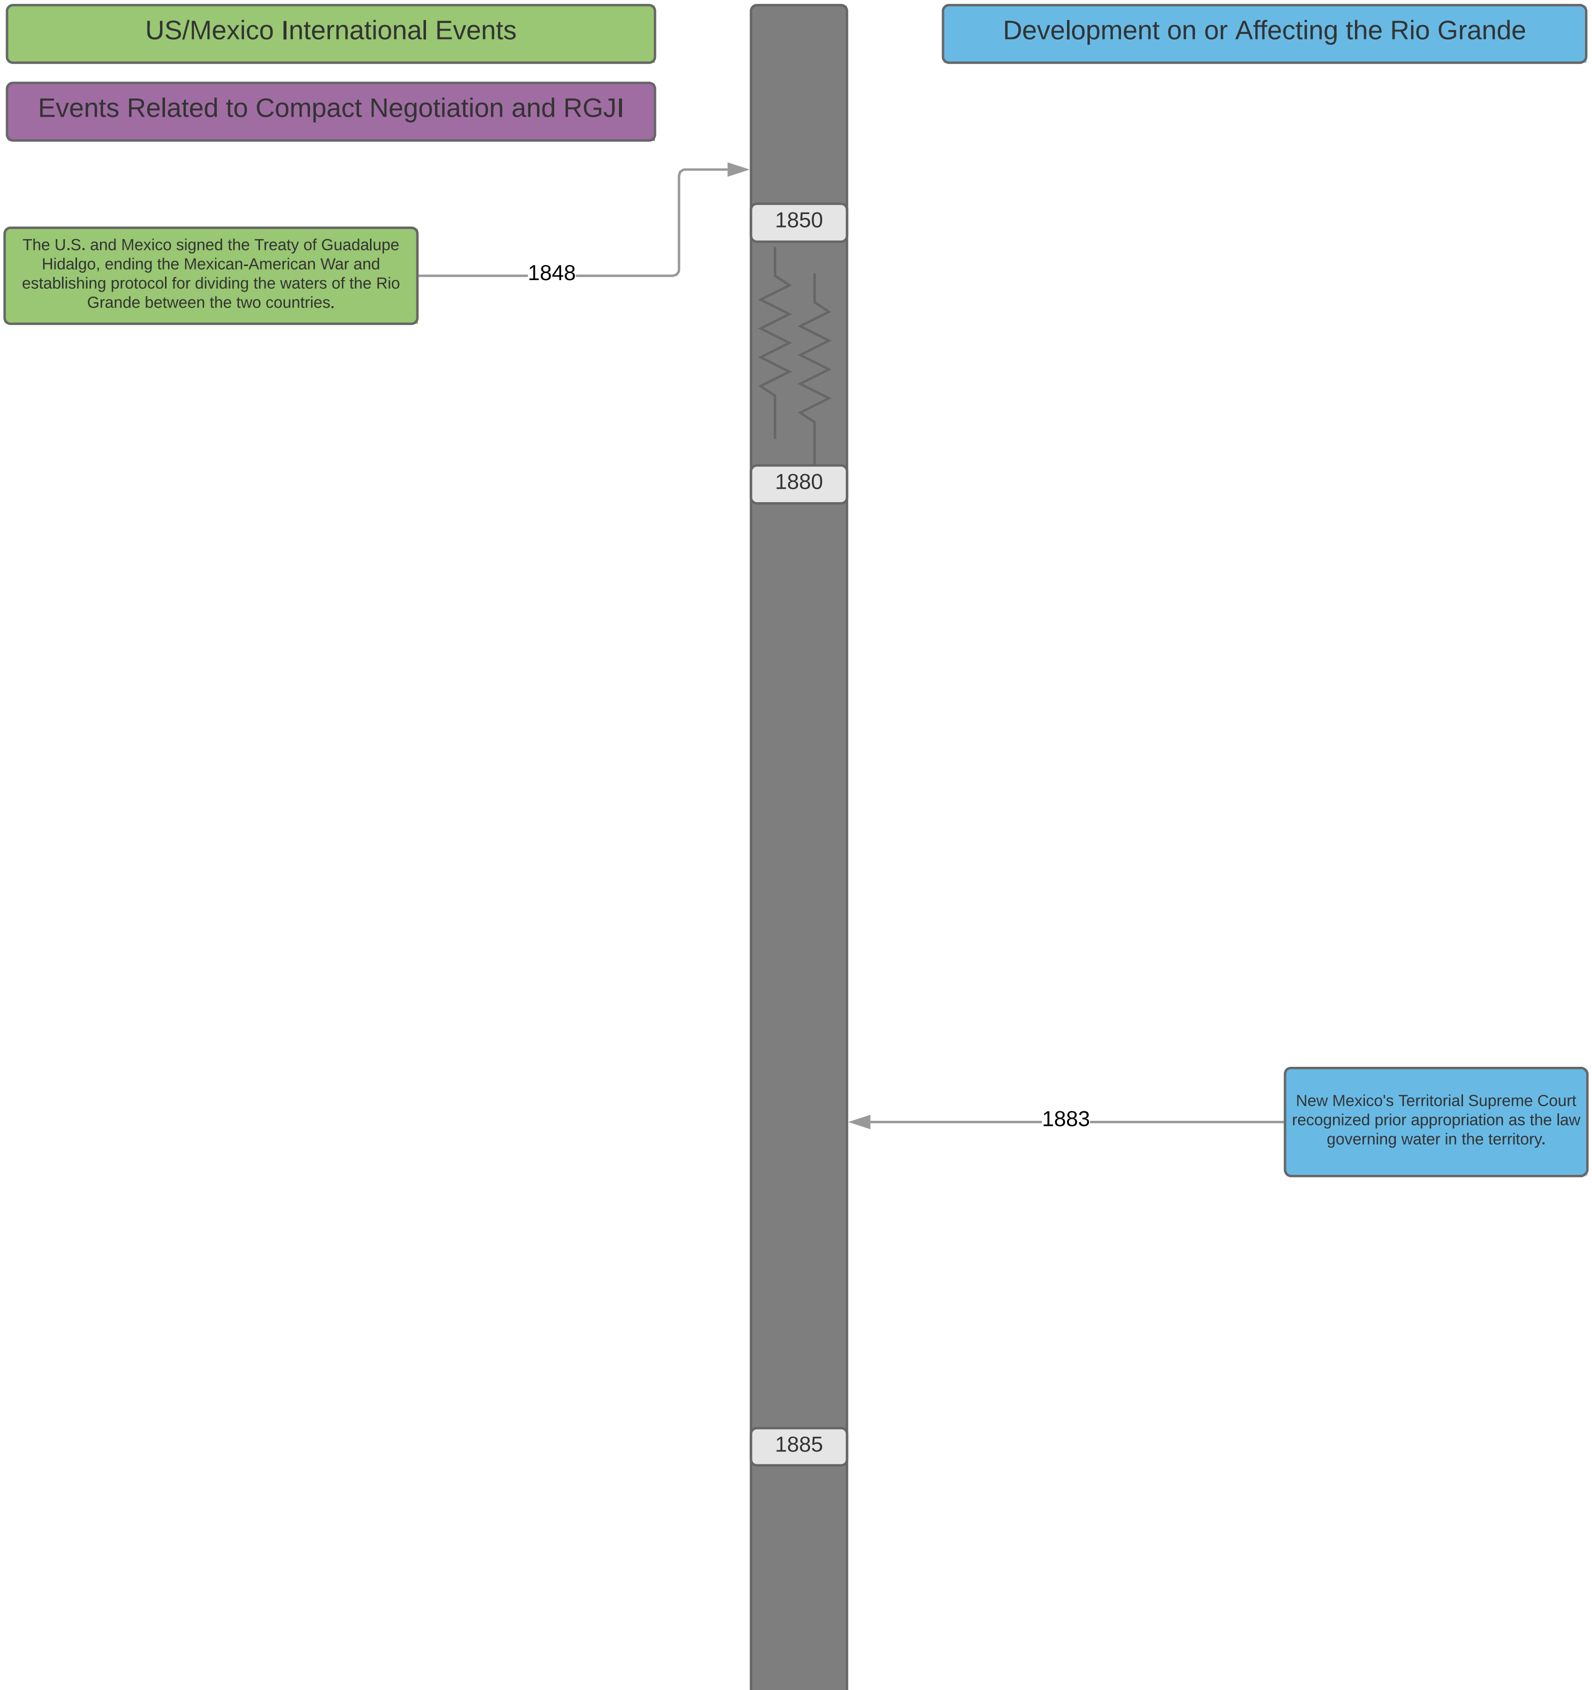
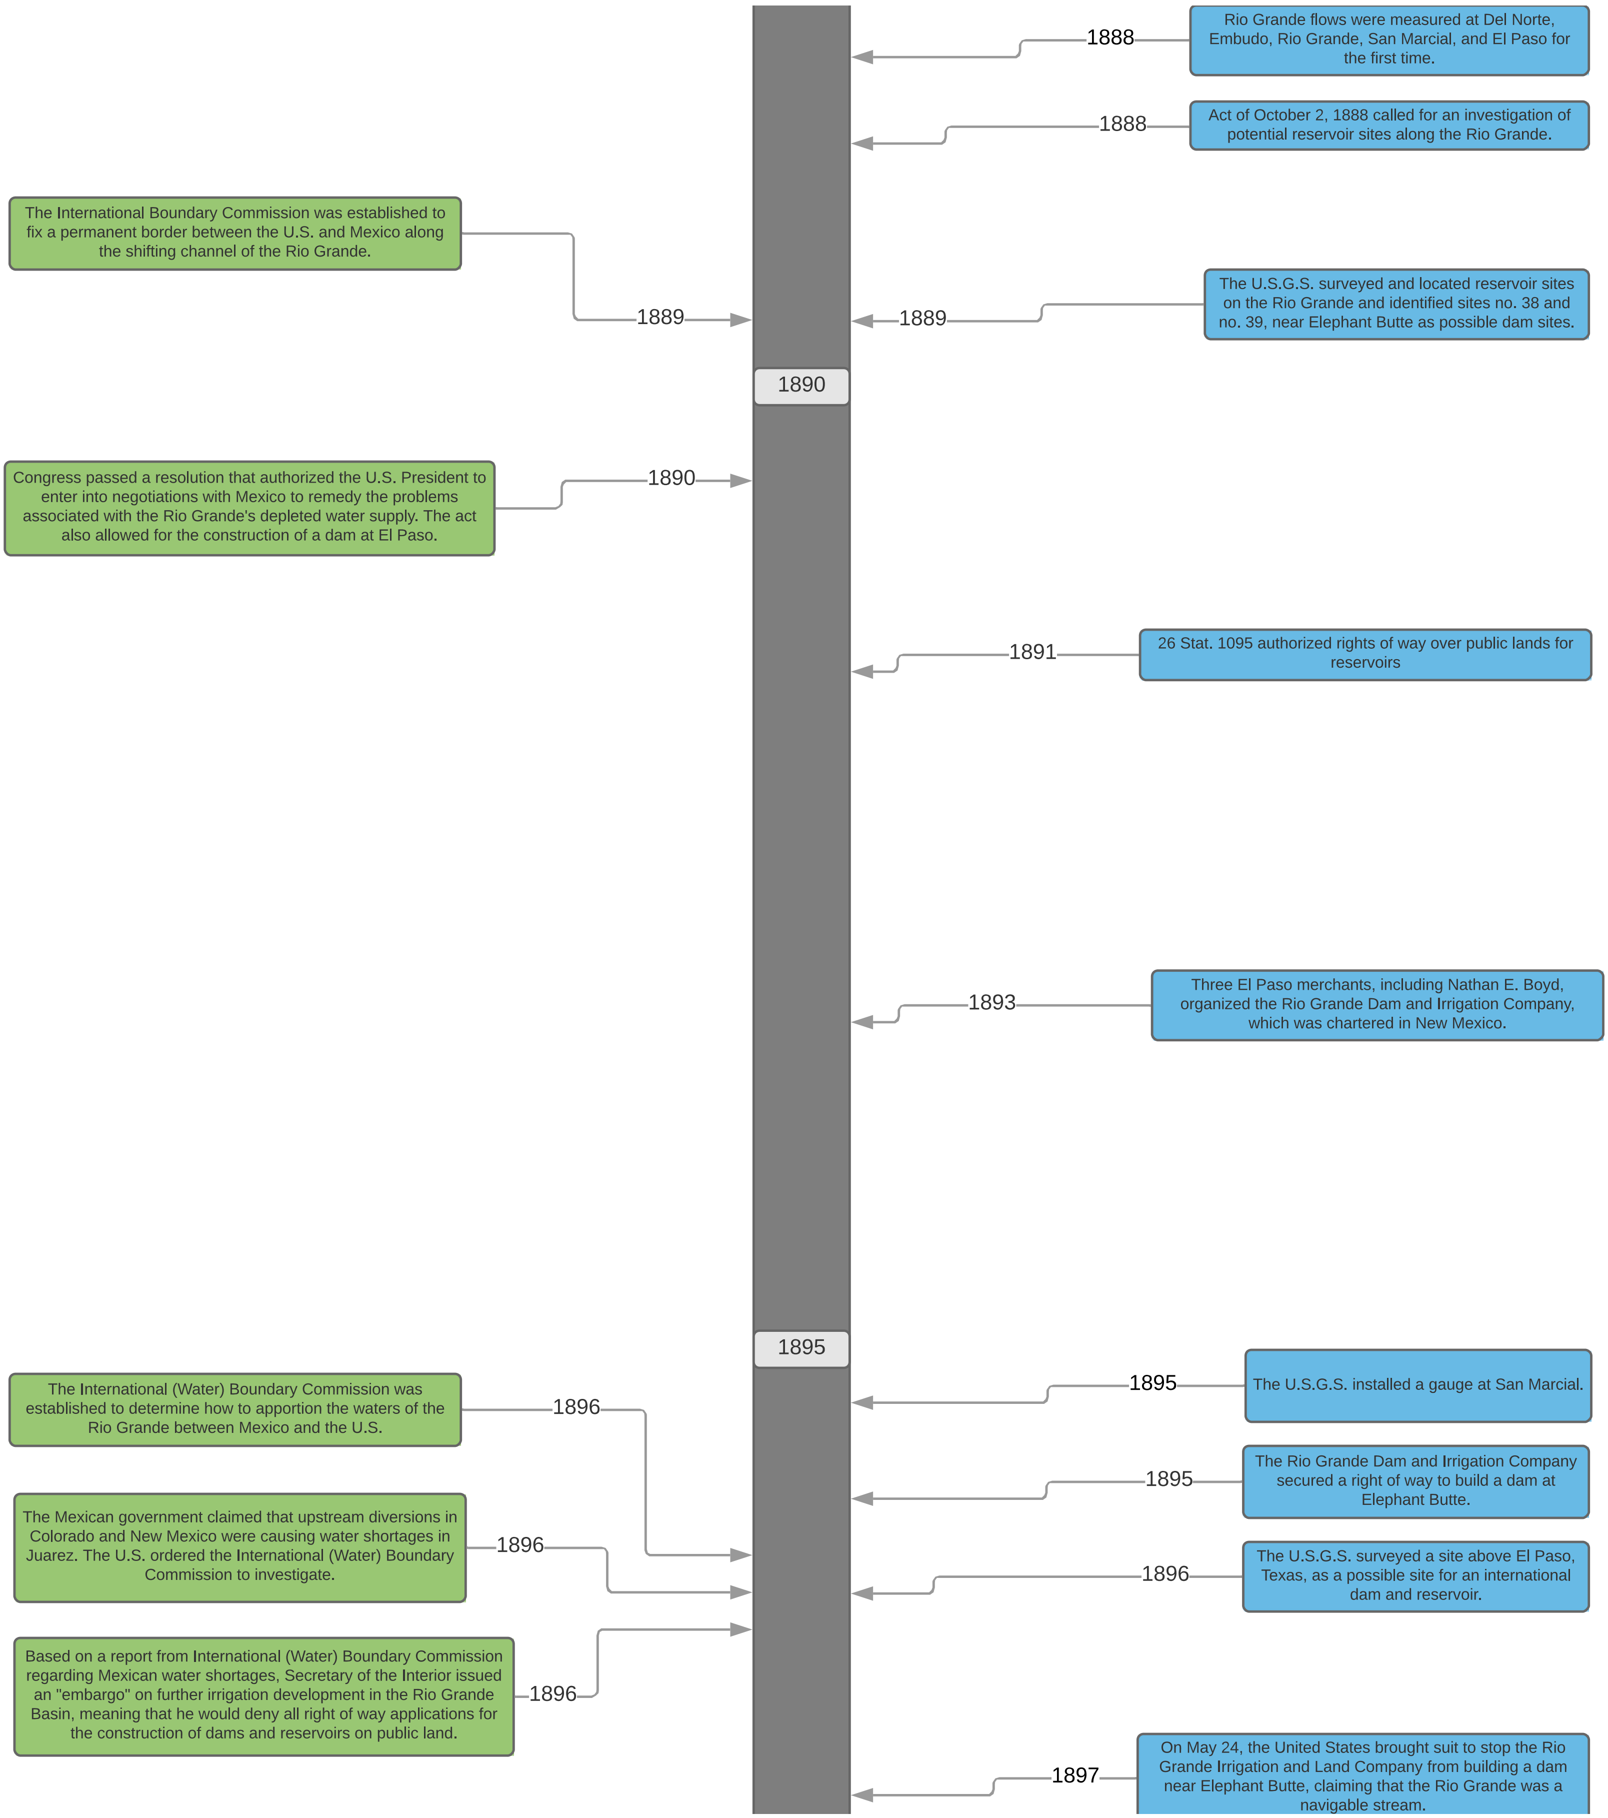
Conclusion

The Upper Rio Grande Basin continued to be a dynamic place from the late 1930s through the 1950s, as the United States made changes to the river itself while also gaining greater understandings of groundwater supplies. Changes to the infrastructure of the Project continued to alter exactly how Reclamation delivered water to the lands within the Project boundaries as well as outside of those boundaries, as did changes to the river that emerged from international diplomacy. As a means of contending with some of that uncertainty, the Project districts signed a contract in February 1938 which provided for a proportionate allocation of water to persist whether in times of drought, fluctuating volumes of irrigated acreage, or changes to the physical river system.

Furthermore, these decades represented a growing understanding of the role groundwater played in the supplies of the basin. The lateness of the groundwater studies in the region below Elephant Butte Dam (in relation to the onset of permanent Compact negotiations) combined with the absence in the historical record of any objection to these studies by water users make it abundantly clear that the Reclamation Service's Rio Grande Project water filings with the New Mexico Territorial Engineer in 1906 and 1908 had not included nor intended to include the basin's groundwater. The scientific understanding of connections between groundwater and surface water was too nascent in the first decade of the 20th century for Reclamation to have intended such an overreach, and the historical record provides no support for such a conclusion. It is also clear that no contemporary actors believed that Reclamation controlled the groundwater. Studies conducted in the 1930s were aimed at a better understanding of the resource's origin in different parts of the basin, its potential use, and possible connections between ground and surface water; these studies would have been unnecessary if water users believed that the Bureau of Reclamation had previously claimed it all. Furthermore, the absence in the historical record of any water users objecting to these studies or to actual groundwater pumping between the 1930s and the 1950s suggests that no one contemporarily believed that the Project owned a prior right to these supplies, nor that Texas's Compact Commissioner would have intended to preclude such resource development in the 1938 Compact. Finally, the Bureau of Reclamation's support and encouragement of Mesilla Valley farmers who turned to pumping as an *additional* supply in response to dwindling surface supplies in the late 1940s and into the 1950s, further emphasizes the Project's lack of a pre-existing groundwater claim. Rio Grande Project histories show that the U.S. Bureau of Reclamation viewed groundwater supplies as an excellent and necessary supplement during times of drought, viewing the lag time between the depletion from underground basins and the consequential effect on surface supplies as a window during which they expected and hoped precipitation and supplies would return to normal, with groundwater recharge taking place before significant surface drafts were realized. Therefore, the federal government encouraged such pumping and the redirection of surface supplies to farmers without access to wells. The pumping by the City of El Paso and the encouragement of groundwater use during the 1940s-1950s drought, in addition to the studies these trends engendered helped boost understanding of the hydrological connections between artesian basins and surface flows, *after* which time groundwater use became an issue which caused controversy at times.

Appendix A: Rio Grande Timeline





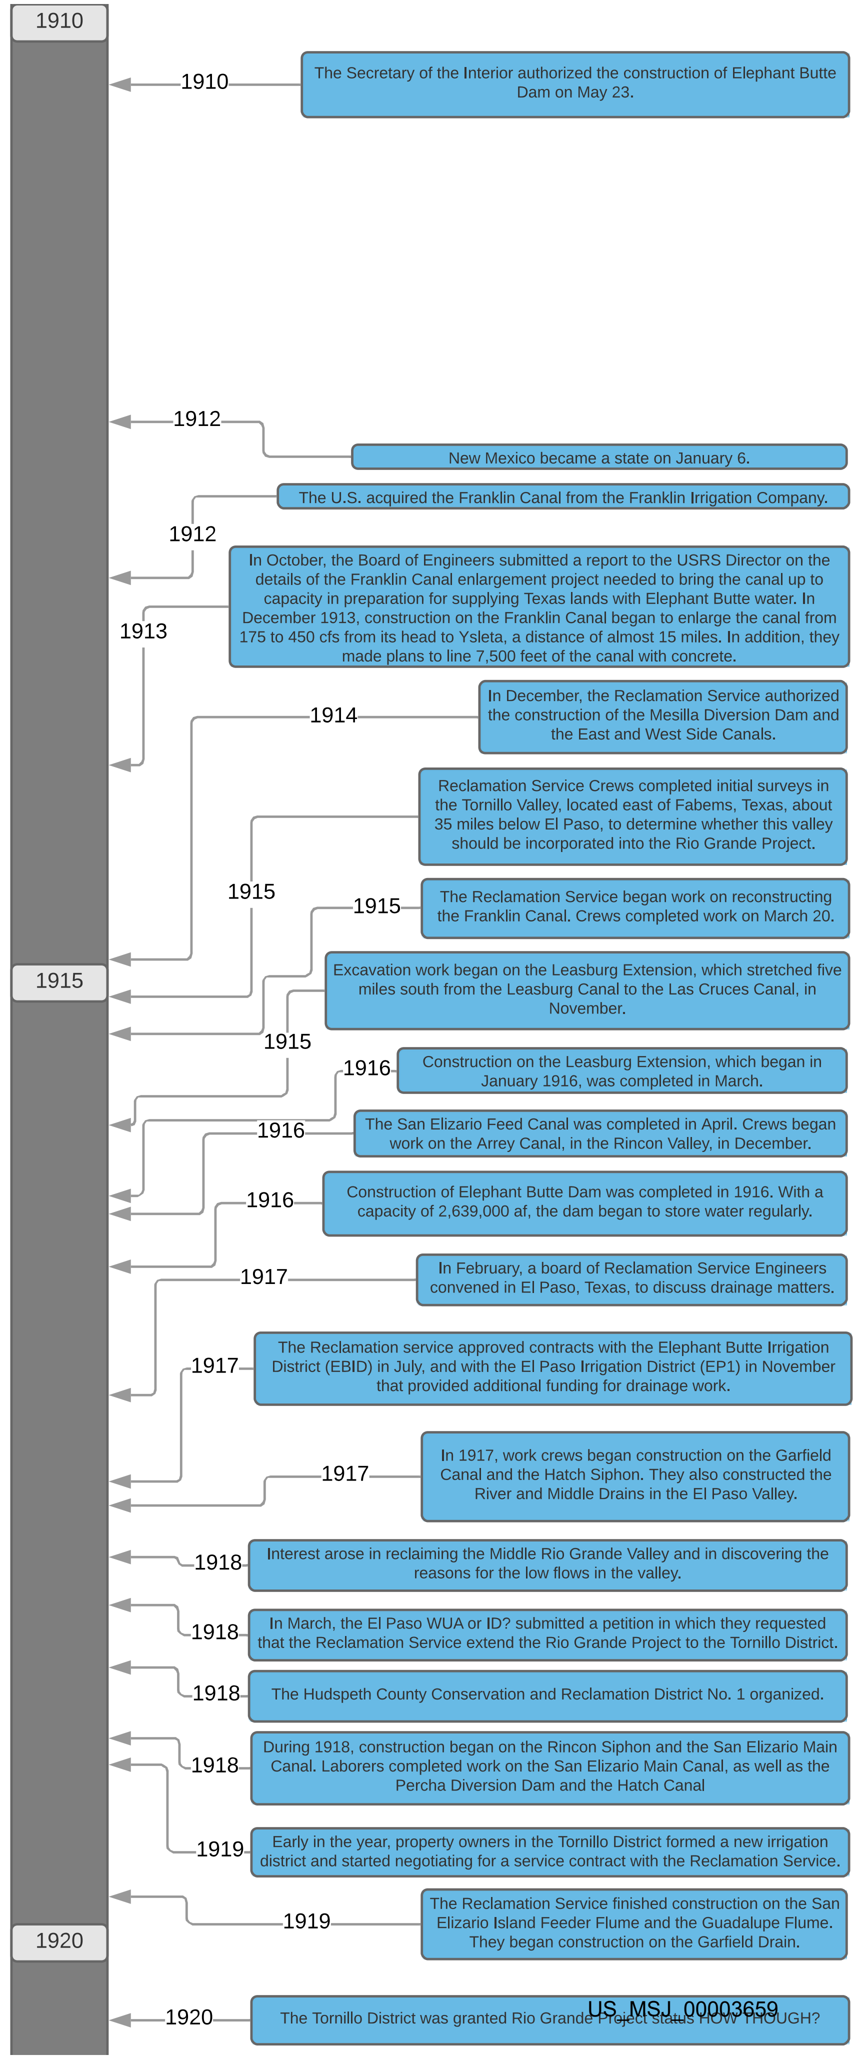
1888 Rio Grande flows were measured at Del Norte, Embudo, Rio Grande, San Marcial, and El Paso for the first time.
1888 Act of October 2, 1888 called for an investigation of potential reservoir sites along the Rio Grande.
1889 The International Boundary Commission was established to fix a permanent border between the U.S. and Mexico along the shifting channel of the Rio Grande.
1889 The U.S.G.S. surveyed and located reservoir sites on the Rio Grande and identified sites no. 38 and no. 39, near Elephant Butte as possible dam sites.
1890
1890 Congress passed a resolution that authorized the U.S. President to enter into negotiations with Mexico to remedy the problems associated with the Rio Grande's depleted water supply. The act also allowed for the construction of a dam at El Paso.
1891 26 Stat. 1095 authorized rights of way over public lands for reservoirs
1893 Three El Paso merchants, including Nathan E. Boyd, organized the Rio Grande Dam and Irrigation Company, which was chartered in New Mexico.
1895
1895 The U.S.G.S. installed a gauge at San Marcial.
1895 The Rio Grande Dam and Irrigation Company secured a right of way to build a dam at Elephant Butte.
1896 The International (Water) Boundary Commission was established to determine how to apportion the waters of the Rio Grande between Mexico and the U.S.
1896 The Mexican government claimed that upstream diversions in Colorado and New Mexico were causing water shortages in Juarez. The U.S. ordered the International (Water) Boundary Commission to investigate.
1896 The U.S.G.S. surveyed a site above El Paso, Texas, as a possible site for an international dam and reservoir.
1896 Based on a report from International (Water) Boundary Commission regarding Mexican water shortages, Secretary of the Interior issued an "embargo" on further irrigation development in the Rio Grande Basin, meaning that he would deny all right of way applications for the construction of dams and reservoirs on public land.
1897 On May 24, the United States brought suit to stop the Rio Grande Irrigation and Land Company from building a dam near Elephant Butte, claiming that the Rio Grande was a navigable stream.

1900

- **1900** — The American Section of the International (Water) Boundary Commission took over operation of the San Marcial gauge on January 1.
- **1902** — From 1892 to 1902, there was a dry period on the Rio Grande, and the river flowed at a third of its usual discharge, with the extreme low flow occurring in 1902.
- **1902** — On June 17, the U.S. Congress passed the Newlands Act (or the Reclamation Act), which sanctioned the federal government's construction of irrigation works and established the U.S. Reclamation Service.
- **1903** — The Reclamation Service began early reconnaissance and preliminary surveys for the Rio Grande Project. They paid close attention to possible dam sites no. 38 and no. 39 identified by the U.S.G.S. in 1889.
- **1904** — The National Irrigation Congress met in January to determine water apportionment of the Rio Grande. They agreed on the Rio Grande Project which included plans for federal construction of dam and reservoir at Elephant Butte. Following the conference, The El Paso Chamber of Commerce established the El Paso Valley Water Users' Association in January, and New Mexican water users met in Las Cruces to create the Elephant Butte Water Users' Association in December. The names of these organizations later changed from Water Users Associations to Irrigation Districts in accordance with state laws.

1905

- **1905** — The U.S. and Mexico signed the Banco Treaty, allowing for the exchange of land no greater than 617 acres when parcels (bancos) ended up on the opposite side of the int'l boundary when the river changed course.
- **1905** — Congress extended the Reclamation Act to the U.S. side of the El Paso Valley on February 25.
- **1905** — In March, New Mexico Territory created the office of Territorial Irrigation Engineer, responsible for overseeing, managing, and administering all water and irrigation related concerns with the territory.
- **1906** — In January, the U.S. Reclamation Service notified the New Mexican Territorial Irrigation Engineer that they intended to store all unappropriated waters of the Rio Grande, 730,000 af per year, in the proposed Elephant Butte Reservoir.
- **1906** — The U.S. and Mexico signed a treaty in which the U.S. agreed to deliver 60,000 af of water to Mexico annually in perpetuity at the head of the Mexican Canal near El Paso. In return Mexico agreed to waive all claims for damages. Congress ratified the treaty on June 26, 1906 and President Theodore Roosevelt approved it on January 16, 1907.
- **1906** — On June 12, 1906 Congress extended the Reclamation Act to include the state of Texas.
- **1906** — On September 27, the Dept. of the Interior issued an order that revoked all prior orders affecting the embargo on the Upper Rio Grande due to the settlement between the U.S. and Mexico in the Treaty of May 21, 1906. The order also mandated that applications involving waters of the Rio Grande in Colorado and New Mexico be directed to the USGS to ensure they would not interfere with reclamation projects or treaty obligations.
- **1907** — On March 4, Congress authorized construction of Elephant Butte Dam, thus creating Eagle Reservoir, and appropriated $1,000,000 for the cost of construction. The dam was to aid in delivering 60,000 acre-feet water to Mexico so the U.S. could fulfill the May 21, 1906 treaty.
- **1907** — In 1907, New Mexico's territorial water code created the Office of Territorial (later State) Engineer, tasked with "administering all matters relating to appropriation, transfer, and distribution of water."
- **1907** — New Mexico Territorial Engineer Frederick Newell issued an embargo preventing right-of-way for the storage of more than 1,000 acre-feet per year above Elephant Butte until there were enough data to understand the effect of upstream development on the Rio Grande project.
- **1908** — The Reclamation Service began surveying for a diversion dam at El Paso.
- **1908** — Authorized in 1905, workers finished construction on the Leasburg unit of the Rio Grande Project, which would irrigate 25,000 acres in the Mesilla Valley, New Mexico.
- **1909** — Litigation in U.S. v. Rio Grande Dam and Irrigation Company ended with the court ruling in favor of the U.S., paving the way for the federal construction of Elephant Butte Dam.



US_MSJ_00003659

1922 — In Februuary, soil experts from the Department of Agriculture studied and reported on the amount of alkali salts in the soil and the effect of drains in the El Paso Valley.

1923 — The Middle Rio Grande Conservancy District (MRGCD) organized.

1923 — In March, Colorado and New Mexico authorized the formation of an Interstate Compact Commission. The states appointed commissioners to study the water supply of the Rio Grande and to draft an interstate compact to address water shortages. New Mexico's first commissioner was J. C. Seth of Santa Fe, and Colorado's first commissioner was Delph E. Carpenter of Greeley.

1923 — In August, the directors of the Hudspeth County Conservation and Reclamation District No. 1 (Hudspeth) requested that the Secretary of the Interior allow them to consollidate with EP1 and operate as a single entity within the Rio Grande Project. This was denied.

1924 — At the first Interstate Compact Commission meeting, representatives of the Texas governor urged the committee to wait to conduct their meeting until 1925, when the Texas legislature could appoint a representative to the commission.

1924 — In December, the Bureau of Reclamation (BOR) and Hudspeth entered into a temporary Warren Act agreement in which the U.S. would supply seepage, waste, and return flow water to the district for the upcoming irrigation season on a rental basis. This water was to be delivered to the end of the Tornillo Main Canal.

1925

1925 — On February 5, the Secretary of the Interior modified an order of withdrawl made in 1896, and confirmed the Vega Sylvestre reservoir site as provided for under the right of way act of 1891.In May, he lifted the embargo against development of the Rio Grande in Colorado, opening the possibility of building additional reservoirs in the state.

1925 — The Texas legislature authorized the appointment of an Interstate Compact Commissioner. The first person to take on that role was T. H. McGregor of Austin.

1925 — The MRGCD was confirmed as legal and constitutional by the New Mexico Supreme Court in a decision handed down on December 12.

1926 — An omnibus bill passed in March authorized EP1 to enter into contract with the BOR covering the investigation and construction of a canal to protect their water supply from encroachment by Mexican diversions.

1926 — During the 1926 irrigation season, the Rio Grande Project watered approximately 80,000 acres in New Mexico, 60,000 acres in Texas, and 25,000 acres in Mexico.

1928 — In April, though 67,000 acres had been planned for, only 58,700 acres were irrigated in the EP1. Despite expansion in 1928, there would still be 4,000 extra acres, and the City of El Paso wanted to purchase the associated water.

1928 — The U.S.G.S. took over operation of the San Marcial gauge on August 8.

1928 — This year, the total irrigated area of the Rio Grande Project was 163,324 acres. of that, 139,598 acres were cropped, and of that cropped area more than 75% was planted with cotton.

1929 — On February 12, Commissioners agreed on a temporary Rio Grande Compact to maintain the status quo in the use of the waters of the Rio Grande and to provide for the accumulation and preservation of data regarding its use. It also acted as a set of guidelines for commissioners in drafting a new compact later on. It was set to expire on June 1, 1935.

1929 — On February 28, Richard F. Burges suggested that the definition of the Rio Grande "above Fort Quitman" be included in the compact because that section of the river was treated as a distinct entity in the 1906 U.S. Treaty with Mexico.

1930

1930 — Burges advised Colorado, New Mexico, and Texas to find an engineer to take charge of "obtaining, collecting, and correlating all data which would be useful both in administering the present compact and in preparing for the new one."

1931 — In 1931, New Mexico began regulating groundwater for the first time. The OSE amended the water code to include groundwater basins and declared them public property "subject to appropriation for beneficial use."

1931 — As a result of altering the Texas-New Mexico state line, 1,000 acres were transferred from EP1 to EBID.

1931 — In August, the International Water Commission took over maintenance and operation of the gaging stations at San Marcial, Courchesne, Tornillo Bridge, and Fort Quitman from the U.S.G.S.

1935

1940

- **1932** — At the start of the year, the U.S. and Mexico signed a treaty to adress the shifting channel of the Rio Grande through the rectification of the channel between El Paso and Juarez, as well as at the head of Box Canyon below Fort Quitman. The convention also allowed for the construction of Caballo Dam about 22 miles below Elephant Butte Dam.
- **1934** — The Rio Grande Compact Committee reaffirmed that the purpose of the 1929 Compact was to maintain the status quo in the use of water of the Rio Grande, and to provide for the accumulation and preservation of data regarding Rio Grande water use.
- **1935** — On February 16, the Gio Grande Compact commissioners signed a bill to extend the life of the 1929 compact for two more years, until June 1, 1937.
- **1935** — On October 28, Texas filed a bill of equity against New Mexico and the MRGCD claiming that New MExico had violated the Compact of 1929 by creating diversions above Elephant Butte that caused an increase in water salinity, which Texas claimed violated its water rights under the doctrine of prior appropriation.
- **1935** — In December, the National Resources Committee hosted a conference with Colorado, New Mexico, and Texas to determine if a cooperative approach to gethering information would result in a solution to the interstate water problems on the Rio Grande. The Commission agreed to let the NRC facilitate the RGJI, and the three states contributed to funding, although the majority of funds came from the federal government (U.S.G.S., BOR, and Bureau of Ag Engineering.)
- **1937** — In March, Engineers from Texas and New Mexico signed a stipulation to continue study on the Middle Rio Grande as well as the area between El Paso and Hudspeth, per request from the Special Master.
- **1937** — RGJI funding expired; studies concludeed.
- **1937** — The Rio Grande Compact Commissioners met on September 27 to consider the Rio Grande Joint Investigation report, confer with National Resources Committee consultants, and formulate a permanent compact.
- **1937** — The Engineer Advisors Committee met in Santa Fe on November 22 for three days to discuss Rio Grande Compact terms.
- **1937** — The final report from the Rio Grande Joint Investigation was submitted to the president. The report provided all interested parties with all essential data as to the sources and quantities of water and information on the development and use of said water.
- **1937** — The committee of the engineering advisers to the Rio Grande Compact Commission submitted a report from their December 1937 meetings. The report covered delivery schedules & related features for the Committee's consideration.
- **1938** — During the month of January 1938, commissioners discuss the Engineer Advisors' Committee Report. They determine that the Engineers should meet again in March to refine some of the numbers and formulas.
- **1938** — On March 15, the Engineer Advisor Committee met to finalize the report on which the new Rio Grande Compact would be based. On March 18, commissioners from Colorado, New Mexico, and Texas signed the 1938 Rio Grande Compact.
- **1938** — The Rio Grande rectification was completed in July.
- **1938** — Frank B. Clayton, Rio Grande Compact Commissioner for Texas, visited the Lower Rio Grande Valley in October to attempt to stem their objections to the compact.
- **1939** — The 1938 Compact became effective May 31. The parties involved dropped the Texas v. New Mexico lawsuit after the ratification of the compact.
- **1940** — 1940 was the first accounting year under the Rio Grande Compact of 1938. During this year N.M. accured a debit of 58,900 acre-feet.
- **1941** — Early in the year, the BOR began an investigation into the possibility of building canals to divert the waste and drain waters of the project directly into the Hudspeth County district for the purpose of preventing Mexican interference with the water supply. The investigation was short-lived as more pressing work arose and project personnel declined.

- **1934** — In October, the Texas Board of Water Engineers and the U.S.G.S. signed an agreement to jointly study the groundwater resources of Texas in 1935.
- **1935** — Begun the previous year, El Vado Reservoir on the Rio Chama, a tributary of the Rio Grande, was completed in 1935.
- **1937** — During A. N. Sayre and Penn Livingstion's visit to El Paso in February, it was decided that the city, through the Texas State Board of Engineers, would participate in an agreement with the U.S.G.S. for an investigation of its groundwater resources.
- **1937** — On July 1, 1937 the USGS and the Texas Board of Water Engineers entered into an agreement for an investigation of the groundwater resources of the State of Texas to run from July 1, 1937 to August 31, 1938. The two entities split the cost evenly.
- **1938** — Begun in 1937, the American Canal in the El Paso Valley was completed ia year later n 1938.
- **1939** — In a July 1939 memorandum...HUDSPETH INFO??? SEE REPORT.
- **1940** — The USGS and the City of El Paso signed a cooperative agreement providing for the continuation of the groundwater investigation in El Paso from July 1, 1940 through June 30, 1941.
- **1940** — In August, Hudspeth applied and was approved for a refinancing and rehabilitation loan so that it could refinance its outstanding indebtedness and pursue much needed rehabilitation works in the district.

1945

1950

1943 — 1943 was the first year that New Mexico failed to meet its water deliveries as stipulated by the 1938 Rio Grande Compact.

1944 — During the 1944 calendar year the BOR worked with the Hudspeth District to draft a contract providing a "permanent water rental basis."

1945 — Correspondence from July 1945 revealed that the all three of the Rio Grande Commissioners (McClure, Hinderlider, and Quaid) as well as U.S. representative Johnson consented to reviewing New Mexico's delivery schedules into San Marcial.

1946 — Berkeley Johnson explained that the Santa Fe District of the U.S.G.S. was to take over operation of the San Marcial gage following the ratification of a new treaty with Mexico.Transfer of operation of the San Marcial gage from the International Boundary Commission to the U.S.G.S. was suspended until Congress made the necessary funds available, which was presumably not going to be until July 1946.

1946 — Extreme drought conditions occurred in the southwest.

1946 — The U.S.G.S. in cooperation with the EBID began conducting a study of the groundwater supply in the Mesilla and Rincon Valleys

1947 — In the spring, a small storage reservoir was built for use by Hudspeth, which necessitated the relocation of the gaguing stations at the end of the Tornillo Canal and at the head of the Hudspeth Canal. A new canal, Hudspeth Feeder No. 1, was constructed to capture project waste water below Fabens and transport it directly to the reservoir without allowing it to reach the river.

1947 — The EBID was “exceedingly anxious” to take action regarding groundwater pumping and hoped to have Conover's groundwater memo released prior the next meeting's date in early October.

1948 — The Rio Grande Compact Commission met at El Paso on February 22 and discussed changing the gaging stations and measurements for the Rio Grande. New Mexico's deliver schedule was changed from a 9-month index to a 12-month index, and became known as the "Elephant Butte Effective Index Supply."

1948 — Congress authorized the Middle Rio Grande Project and gave permission to the Bureau of Rec. and the Corps of Engineers to rectify the Rio Grande channel, rehabilitate works of the MRGCD, construct levees, and other dam and reservoir projects.

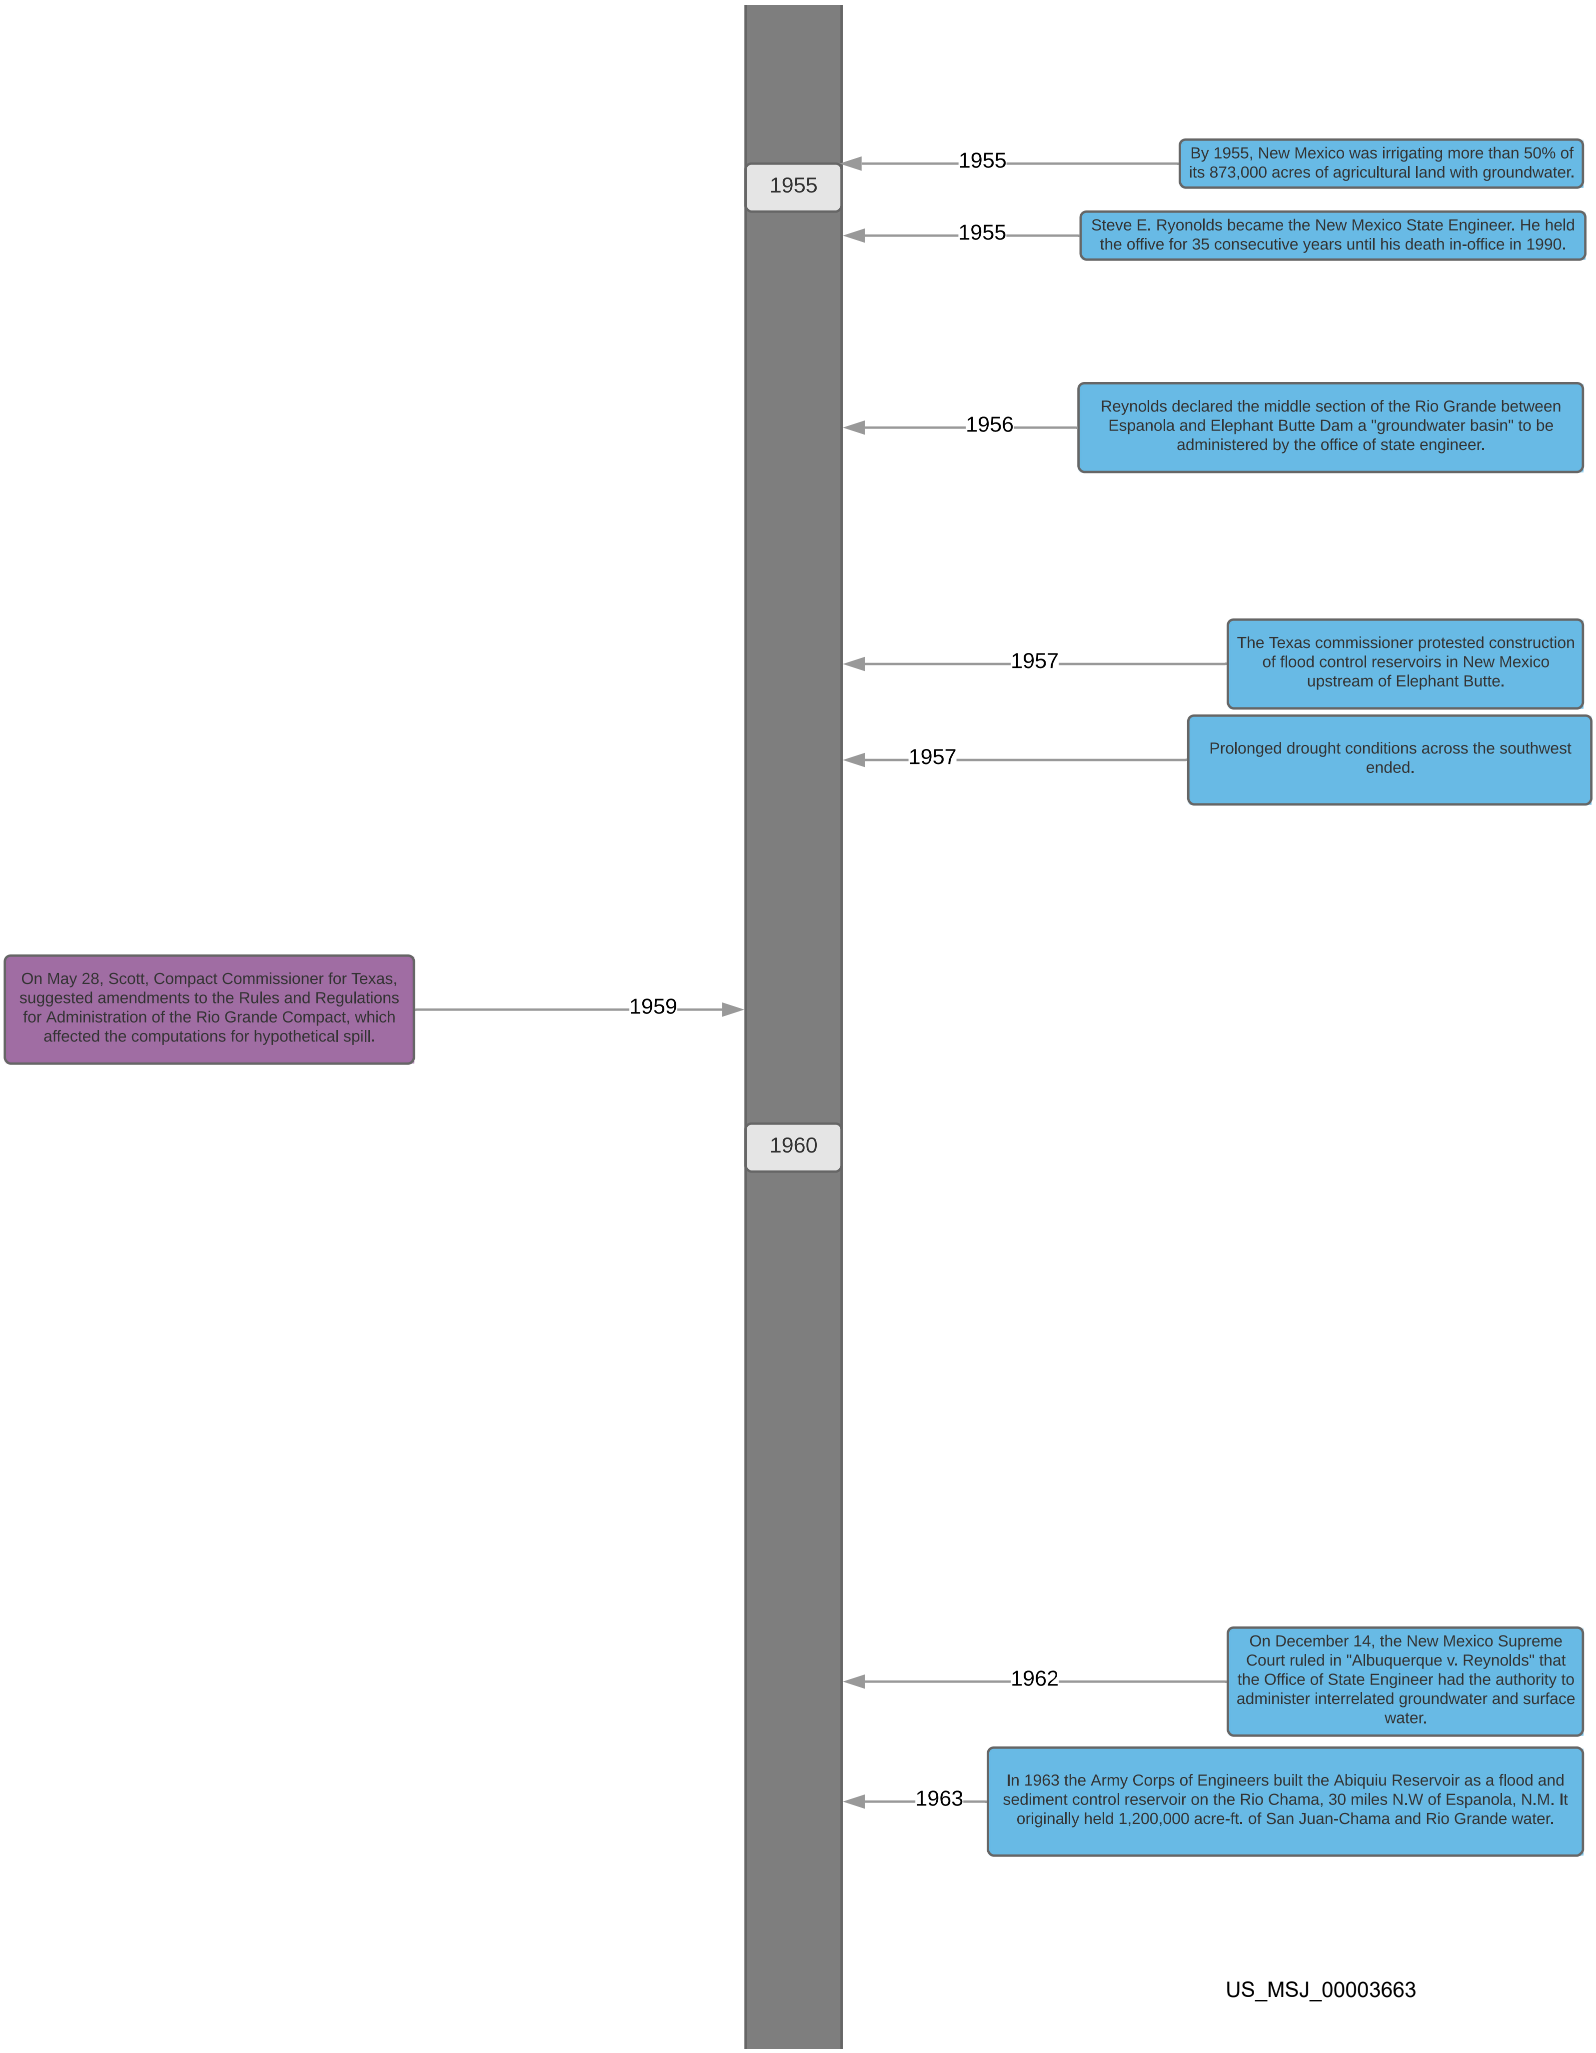
1950 — Prolonged drought conditions began in the southwest.

1950 — On December 28, Raymond Hill wrote to the El Paso County Water Improvement District No. 1 and acceded that the release of debit water from El Vado Reservoir was not adverse to the interests of Rio Grande Project water users.

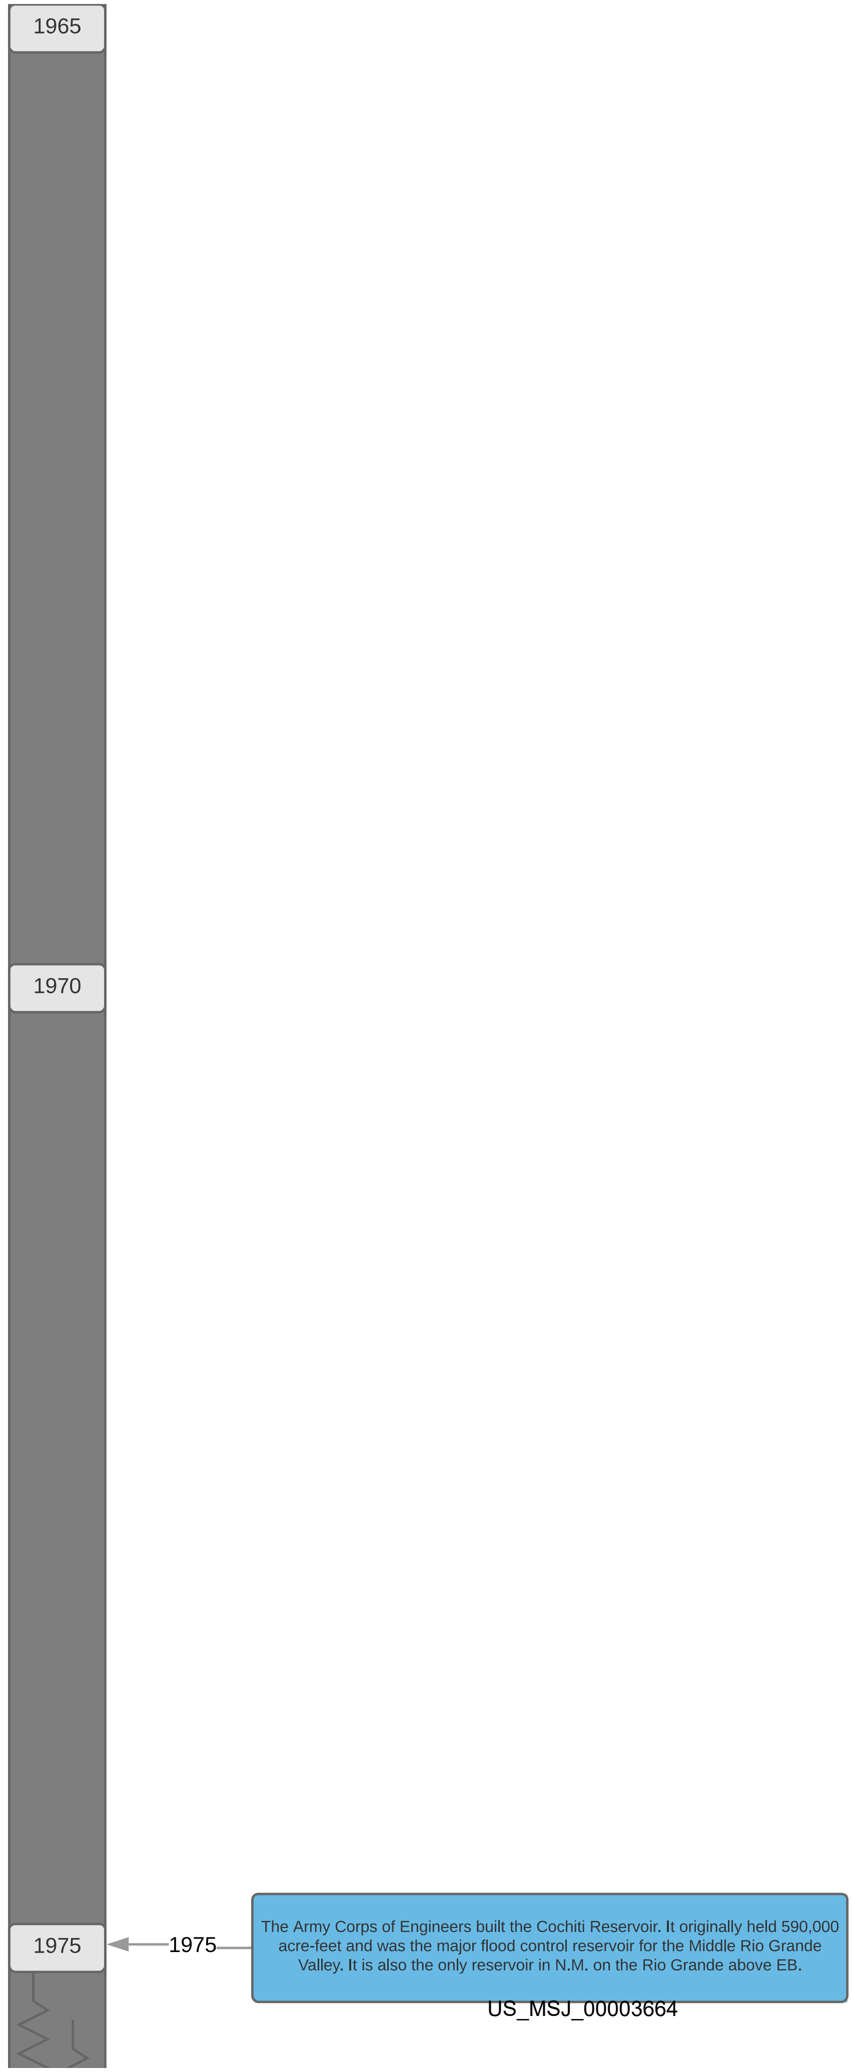
1951 — MRGCD Engineer Hubert Ball foresaw completing the MRG project as the only means of remedying the drought situation. This project would drain the San Marcial swamps and end “wastage of 70,000-100,000 acre feet of water” each year.

1951 — In October, Texas filed a complaint against New Mexico in the U.S, Supreme Court, claiming that New Mexico violated the Rio Grande Compact of 1938 and asking that New Mexico be prevented from diverting waters above San Marcial.

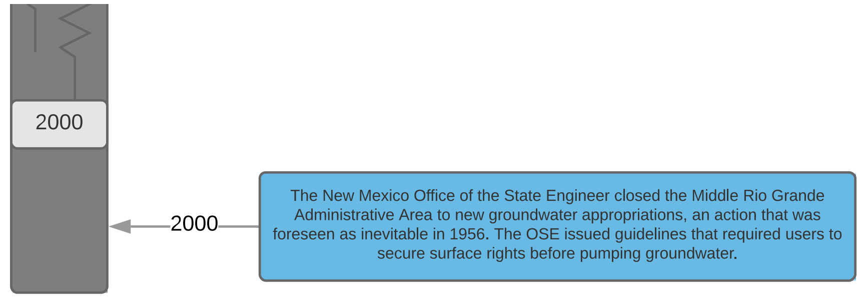
1953 — MAYBE: THEIS GROUNDWATER STUDY



US_MSJ_00003663



1965
1970
1975
1975
The Army Corps of Engineers built the Cochiti Reservoir. It originally held 590,000 acre-feet and was the major flood control reservoir for the Middle Rio Grande Valley. It is also the only reservoir in N.M. on the Rio Grande above EB.



2000
2000
The New Mexico Office of the State Engineer closed the Middle Rio Grande Administrative Area to new groundwater appropriations, an action that was foreseen as inevitable in 1956. The OSE issued guidelines that required users to secure surface rights before pumping groundwater.

Experience

Dr. Stevens is an urban/environmental/industrial historian. She offers expertise and historical consulting on a range of issues related to land and water use to private, public, and Native American clients across the country. She has researched and written extensively on issues related to water rights, stream navigability, irrigation facility development, land use and settlement, forest management, storm water disposal, mining development, mine waste disposal, historic surveys and boundaries, and Superfund liability and clean-up. Dr. Stevens is active in the history profession as well as civic matters, serving on professional committees and government commissions, including the governor-appointed Idaho State Historical Records Advisory Board and mayor-appointed City Planning and Zoning Commission.

Education

Ph.D., American History University of California, Davis. 2008.

Dissertation: Feminizing the Urban West: Green Cities and Open Space in the Postwar Era, 1950-2000

M.A., American History University of California, Santa Barbara. 1995.

B.A., History and Political Science University of California, Santa Barbara. 1993.

Skills

Archival research, writing, editing, expert witness work, oral histories, cultural resource management and Section 106 compliance, project management, public speaking.

- State Archives: California, New Mexico, Arizona, Idaho, Oregon, Kansas, Washington, Oklahoma
- Special and Academic Collections: Huntington Library, Bancroft Library, many others
- Corporate Archives: Salt River Project, PG&E, J.R. Simplot Company, Idaho Power Company, others

Select Clients

Land O'Lakes; CBS/Viacom; J.R. Simplot Corporation; FMC; Idaho Power; Idaho Department of Lands; Tesoro/ Andeavor; British Petroleum (BP); multiple Idaho counties; Idaho Attorney General; New Mexico Attorney General; State of Washington Department of Ecology; Boise Project Board of Control; Pioneer Irrigation District; North Dakota County Consortium; U.S. Forest Service

Project History – Consulting/Litigation

Water Rights/Irrigation

2016-2017: Consulting historian for large landowner in California, researching the water rights, title history, and land use of a historic Central Valley Ranch dating to the mid-19th century. Produced lengthy report for potential use in future litigation.

2014-2018: Consulting historian for water users in Water District 63, the Boise River Basin. Conducted research on history of flood control and irrigation operations for use in Snake River Basin Adjudication late claim dispute with state over water rights. Testified at state agency hearing. *(SRBA Subcase Nos. 63-33732, 63-33733, and 63-33734)*

2013-present: Expert historian for Attorney General of New Mexico related to the history of interstate water use in *State of Texas v. State of New Mexico and State of Colorado No. 141, Original*.

2012-2015: Consulting historian for Nampa & Meridian Irrigation District in Idaho. Providing research on the history of the district, its facilities, and the historic (natural) state of the land and watercourses in the district for use in TMDL preparations and other Clean Water Act compliance. See report here: http://www.shraboise.com/wp-content/uploads/2015/04/Water-in-the-Boise-Valley-NMID.pdf

2012: Consulting historian for eastern Idaho canal company. Provided research on the history of Carey Act water development and water rights administration on the project. Dispute settled out of court.

2008-2013: Consulting historian/expert for Pioneer Irrigation District in *Pioneer Irrigation District v. City of Caldwell* (CV-08-556-C). Provided expert deposition testimony, primary historical research and authored a report on the history and development of the Irrigation District's facilities.

2009-2010: Expert historian for Boise City Canal Company in *Corn, et. al v. Boise City Canal Company.* Provided research on the historical construction of Boise City Canal Company's canal for use in litigation over damages. Case was settled out of court in 2011.

2008-2011: Expert historian for Settlers Irrigation District in *Ada County Highway District v. Settlers Irrigation District* (CV-0C-0605904). Provided expert testimony in deposition and an expert report regarding the history of the Settlers' canal system, land settlement in Ada County, and the historic presence of water in the area in question. Judge issued a favorable ruling on summary judgment motion with heavy reliance upon SHRA expert report. Case was settled out of court in 2011.

2010: Expert historian for Pioneer Irrigation District (Idaho) regarding water rights issues for the *Snake River Basin Adjudication.* Researched the District's water rights history in relation to other adjacent users.

2010: Expert historian for Middle Fork Holding Company in *Middle Fork Holding Company v. United States* (CV09-440-CWD). Provided research and expert report on the history of the Middle Fork Lodge's Challis National Forest holdings, including irrigation ditch being litigated as a potential R.S. 2339 canal. Case was settled out of court in 2010 in favor of client.

2007: Consulting historian for Surface Water Coalition in south central Idaho in the matter *of A&B Irrigation District et al. v. Idaho Department of Water Resources, et al* (Fifth Jud. District Case No. CV-2008-55I). Provided historical research on the development of water resources in south-central and south-eastern Idaho. Research included the history of ground water as well as surface water use developments.

2005-2007: Consulting historian for ERO resources in Boise, Idaho. Authored a consulting report entitled *The History of Water and Land Use in the Twin Falls, Idaho Region, 1870-1990*, for use in a legal dispute between water users in south central Idaho.

1998: Associate Historian and consultant for State of Kansas in litigation matters regarding the Republican River Compact and interstate Republican River adjudication.

1998: Associate Historian and consultant for water users in ongoing adjudication of the Snake River Basin. Provided research on the effects of Upper Snake River Dams on downstream salmon migration for use in legal conflict between Nez Perce Indians and water users.

1997-1998: Associate Historian and consultant for a municipal entity involved in the Rio Grande River Adjudication. Provided research and writing on early land and water use around the modern city limits, including groundwater, to determine municipal usage rights.

1997-1998: Associate Historian and consultant for Fort Hall Irrigation Project water users in Idaho, involved in water rights contract with the United States. Provided research on water right contract issues between the water users association and the United States.

1997-1998: Associate Historian and consultant for Kern Delta Water District regarding the historical water rights on the Kern River. Provided research and writing on the history of the famous *Lux v. Haggin* case and its subsequent agreements in order to determine Kern Delta's rights.

1996-1998: Associate Historian and consultant for the state of Idaho regarding the Snake River Basin Adjudication. Provided historical research on water rights of the Snake River islands located in the Deer Flat National Wi1995-1998: Associate Historian and consultant for Nebraska Department of Water Resources. Provided research on the history of *Nebraska v. Wyoming*, 325 U.S. 589 (1945), for use in litigation between Nebraska and Wyoming over the apportionment of North Platte River waters.

1995-1998: Associate Historian and consultant for federal client. Providing research on the history of *Rancho Santa Margarita v. Vail* for use in a water dispute over the Santa Margarita River in southern California.

Navigability

2017-2018: Consulting historian for Idaho Department of Land on a navigability study of 147 waterbodies throughout the state. To be completed in July 2018.

2015-2017: Consulting historian for the State of Idaho Department of Lands on a historic navigability study on the Weiser River in southern Idaho. Produced report opining on the river's navigability at statehood.

2016: Consulting historian for private client regarding the navigability of the Big Wood River. Dispute settled out of court.

2013-2016: Historian for State of Idaho Attorney General. Researched the historic navigability of the Payette River from Idaho's territorial period to statehood for litigation purposes. Case settled out of court favourably for the State.

2012-2015: Consulting historian for public utility. Researched and authored report on a river's historic navigability as it related to legal consideration of river beds and banks ownership. (Client confidential.)

1995-1998: Associate Historian and consultant for the Salt River Project (Arizona). Provided research on the commercial navigability of the Salt River, Gila River, and Verde River at the time of statehood (1912) for use in hearings in front of the Arizona Navigable Stream Adjudication Commission.

CERCLA/Superfund

2019: Expert historian for confidential client/Potentially Responsible Party, Land O' Lakes. Conducting research and writing expert report related to the history of waste management at a legacy oil and gas refinery in Oklahoma.

2018: Expert historian for Pioneer Natural Resources in related to liability on CERCLA site in the Creede mining district, Colorado. Provided original research, an expert report, and expert deposition testimony in September 2018. (*United States v. Pioneer Natural Resources Company* et al, Civil Action 1:17-CV-00168-WJM-NYW) Settled out of court favourably to SHRA's client.

2017-2018: Consulting historian for Potentially Responsible Party on a New York-area CERCLA site. Provided research and document discovery related to federal government contracts during World War I and World War II.

2015-2016: Consulting historian for Potentially Responsible Party on a 19th century western mining site (confidential) concerned with a surface water pathway. (Nevada)

2013-present: Historian for British Petroleum/Atlantic Richfield on a legacy CERCLA lead refinery site. Providing research on potentially responsible parties and historic corporate relationships.

2013-2015: Consulting historian for Potentially Responsible Party on Duwamish Waterway CERCLA site near Seattle, Washington. Researching the history of land use and water pollution during the 20th century. (Client confidential.)

2012-2018: Expert historian for defendant in litigation over liability for an Oklahoma CERCLA site in *Cyprus Amax Minerals Company v. TCI Pacific Communications and CBS Operations, Inc. (11-CV-252-JED-PJC)*. Researching potentially responsible parties, direct operator liability, and corporate relationships at the legacy site in a "piercing the veil" (phase one) and direct liability/allocation (phase two) case. Provided expert deposition testimony twice and testified at trial in February 2018.

2011-2014: Expert historian for mining company on the history of operations at a western mine site to determine liability under a CERCLA claim. (Client confidential.) (Idaho.)

2010-2013: Expert historian for Colville Confederated Tribes in *Joseph A. Pakootas, et al v. Teck Cominco Metals, Ltd.* (CV-04-0256-LRS), a civil action involving CERCLA claims against a mining company in eastern Washington State on the Columbia River. Provided comprehensive expert rebuttal report and deposition testimony regarding the history of mining in the region.

2008-2012: Consulting historian for mining company in eastern Idaho, regarding the history of river pollution and land use on a CERCLA-regulated site. Authored a comprehensive history regarding Resource and Conservation Recovery Act (RCRA) and CERCLA (Superfund) regulation and corporate land use on the site.

1999: Assistant Historian for Quivik Consulting Historian, Inc. Provided research and writing on mining history for the *Bunker Hill Superfund* litigation (*United States v. ASARCO, et al*) in northern Idaho, with particular attention to liability and corporate ownership issues.

1999: Assistant Historian for Quivik Consulting Historian, Inc. Provided research and writing on mining history for *Pinal Creek Group v. Newmont Mining Corp., et al.,* in Arizona.

1998: Associate Historian and consultant for the Sacramento Municipal Utility District (SMUD) in litigation *SMUD v. CalTrans, et al.* Provided research on the historical land use of a contaminated site adjacent to the Sacramento River to determine clean-up liability.

Native American Reservation History

2019: Consulting historian for Midwestern state regarding native use of significant waterway and treaty intent and understandings related to water use. (Client confidential.)

2017-present: Consulting historian for private entity regarding original Northwest Tribe's reservation boundary and Indian Claims Commission history. (Client confidential, Washington)

2015: Consulting historian for Skokomish Tribe regarding potential fishing and hunting litigation. Provided research on tribal history and aboriginal territory, as well as reservation boundaries. (Washington)

2013-2016: Expert historian for FMC Corporation on the Eastern Michaud Flats CERCLA site (phosphate processing) in Idaho for hearing in Tribal Court over matters relating to jurisdiction. Researching the site's Native American, corporate, river, and other land use and title history. Provided expert deposition testimony in *2014: Shoshone-Bannock Tribes Land Use Department and Fort Hall Business Council vs. FMC Corporation (C-06-0069, C-07-0017, C-07-0035)*, and trial testimony in 2015.

2010-2014: Consulting historian for a privately held mining company in the State of Washington in a dispute with the federal government over Indian Reservation boundary. Issues include historic creek location and historic treatment of lands bordering a creek in Washington State. (Client confidential)

R.S. 2477/Road Right of Way/1866 Mining Act

2019: Consulting historian for private landowner. Researching access history related to multiple roads on landowner's properties. (Idaho)

2015-2018: Expert historian for Attorney General of the State of New Mexico in a dispute over public roads in *David Stanley v. Board of County Commissioners of Mora County, et. al. (D-809-CV-2011-00252)*. Conducted archival research and prepared expert report and expert testimony at trial. Testified for three days in March 2018.

2015-present: Consulting historian for a consortium of counties in North Dakota in dispute with the U.S. Forest Service over historic roads. Researching the historic travel routes in the area as well as historic land use and economic development in the region dating back to the mid-19th century. Authored expert report and rebuttal report. Provided deposition testimony in May 2018.

2017: Consulting historian for private landowner in a dispute with county over road access in Valley County, Idaho. Provided research that assisted in settlement of dispute.

2017: Consulting historian for private landowner in a dispute with county over road access along Priest Lake in northern Idaho. Provided research and opinion regarding road history.

2015: Consulting historian for Franklin County, Idaho. Provided research and an expert report on the history of a rural road and settlement – Mink Creek Road – whose access was disputed.

2015-present: Consulting historian for State of New Mexico regarding history of state roads and public access.

2012: Consulting historian for Bear Lake County, Idaho, regarding historic roads for use in R.S. 2477 road validation proceedings under the 1866 Mining Law. Provided research on local land use and historic travel routes. Dispute settled out of court.

2010-2013: Consulting historian for Washington County, Idaho regarding the historic presence and use of roads in the County for use in R.S. 2477 road validation proceedings under the 1866 Mining Law. Provided expert testimony at a public hearing held in May 2012.

2010-2011: Expert historian for Baker City in *City of Baker City, OR v. United States of America, et al (*Civil No 2:08-cv-717-SU) regarding the historic presence of mining ditches in the surrounding National Forest for use in validation of ditch as an R.S. 2339 right-of-way under the 1866 Mining Law. Offered expert testimony and an expert report that were used for a successful trial outcome for Baker City in October 2011.

2009-present: Consulting historian for Valley County, located in central Idaho. Providing historical research on the presence of roads on federal land for potential litigation of R.S. 2477 roads claim under the 1866 Mining Law.

Other

(Public Health/Asbestos) 2016-2018: Consulting historian for large manufacturing corporation in its defense against asbestos claims. Researching and writing a corporate history, examining product development, government regulations and understanding related to asbestos use, mergers and acquisitions, and the history of the industry for contextual purposes.

(State Lands) 2017-present: Consulting historian for western state regarding history of state land management.

(Clean Water Act) 2010-2011: Expert historian for defendant in *United States of America v. Michael Rodriguez* (CR-09-279-S-BLW) regarding potential Clean Water Act violations. Issues include the historical nature of the land and the existence of wetlands thereupon. Provided expert report which helped settle this dispute out of court.

(Land Use/State Lands) 2012-2013: Consulting historian for State of Idaho Attorney General regarding historical management of state cottage site lands. Produced expert report; case settled out of court.

2010-2011: Consulting historian/grant writer for Boise State University. Worked with faculty members in the College of Social Sciences to write interdisciplinary grant materials for National Science Foundation funding related to water and land use in the Boise River Basin, Idaho.

(Mining) 2010: Consulting historian for Sima Muroff/Blackhawk on the River on the historical impact of the War Production Board's L-208 regulation closing all "non-essential" mines in the United States in 1942. Provided research and report on Idaho mines affected by order L-208.

(Land Use) 2003-2004: Consulting historian for City of Boise, Idaho. Authored a report entitled *Land Use and Conservation in the Boise Foothills, 1862-2001* for use in support of federal legislation dictating the terms of a land exchange between various state, federal, and local entities.

Cultural Resource Management and Other Public History

Exhibit/Museum Consulting

2017-present: Consulting historian, photo curator, and editor for museum exhibit on the history and role of geothermal resources in the development of Boise, Idaho at the Boise WaterShed Environmental Education Center.

2015-present: Consulting historian for Harris Ranch and Harris Family, Idaho. Conducting research on the history of the Barber Valley, the Harris Family business, and more recent urban development to author a book for publication due in late 2019.

2014-2016: Project historian for Idaho Power Company and managing the company's year-long centennial celebration throughout 2016. Providing research, project planning, writing, online and traditional exhibit planning, oral history, and documentary expertise. The project received the National Council on Public History's Award for Excellence in Consulting in 2017.

2012: Historian for the Idaho Education Association. Authored a 120-history of the teachers' union that was published and received Honorable Mention for Excellence in Consulting from the National Council on Public History.

National Historic Preservation Act Section 106 Mitigation

2016-2017: Consulting historian for the Idaho Transportation Department. Research and authored a history of travel routes along the Little Salmon River in central Idaho. Produced historical report approved by the State Historic Preservation Office.

2015-2016: Consulting historian for the Idaho Transportation Department. Researched the history of ferry transport on the Snake River to mitigate the loss of a historic bridge.

2010: Consultant to City of Boise. Authored the City's new Historic Preservation Plan. This project represented the first revision of the City's plan since the original was written in 1979.

Conference Presentations and Other Professional Talks

March 2019: National Council on Public History. Panel facilitator, "What You Need to Know About Consulting."

April 2018: National Council on Public History. Workshop leader and Roundtable Participant (two sessions) on "The Nuts and Bolts of Historical Consulting," and "Sustaining Your Consulting Business."

October 2017: Society for American City and Regional Planning History. "From Blue to Green: Boise's Industrial Past and Sustainable Future." Gave presentation on industrial history, brownfields, and greenwashing the Intermountain West. Cleveland, OH.

March 2017: American Society for Environmental History. Participant in panel entitled, *Changes in the Professional Landscape: Preparing Students to Practice Interdisciplinary Environmental History.*

October 2016: Presenting the history of Idaho Power Company at the Annual Meeting of the Western History Association on a panel entitled: *100 Years of Electricity in the West: Utilities and Their Publics*, St. Paul, MN.

April 2016: Invited and featured speaker for graduate students participating in the Mellon Public Scholars Program at the University of California, Davis.

March 2016: Presented research on the history of Idaho water at the Annual Meeting of the Society for Environmental History on a panel entitled: *Environmental Historians Doing Public History: Working with Agencies and Communities to Protect Ecosystems and Landscapes*, Seattle, WA.

January 2013: American Historical Association. Participant in panel entitled, *The Entrepreneurial Historian*. New Orleans, LA.

March 2010: American Society for Environmental History. Roundtable Organizer, *Alternate Voices, Shared Visions: Women in Post-WWII Environmentalism*. Portland, OR.

March 2010: Women's History Month speaker for Boise civic series put on by Boise State University's Center for History and Politics entitled Fettuccine Forum. Boise, ID.

October 2009: Western History Association. "The West is Healthy?: Smog and Its Impact on the Cities of the West: 1950-1980," as part of the panel, *Wiring Wellness in the West*. Denver, CO.

October 2009: Planning History/Society for American City and Regional Planning. "Telesis: A Roundtable." Presented research on Dorothy Erskine's role in what was a cutting edge planning group out of Berkeley, CA. Oakland, CA.

May 2009: Foothills Learning Center Sunset Series. "Hull's Angels: The History of Western Women and Open Space Campaigns." Boise, ID.

April 2009: Western Association of Women's Historians. "Living on the Edge: Hillside Women's Plans for a Wild Los Angeles, 1955-1970," as part of the panel: *Defining Los Angeles: A City's Identity in Flux, 1880-1980*. Santa Clara, CA.

March 2009: U.S. Bureau of Reclamation. "Women of the Urban West, Green Cities and Open Space

Battles in the Post War Era," in honor of Women's History Month. Boise, ID.

June 2008: Berkshire Conference on the History of Women. "Saving Us from Subdivisions and Giving Us Space: Women as Environmentalists in the Early Second Feminist Era," as part of the panel: *Battling Urban Sprawl, Pollution, and Poverty: Justifications for Women's Environmental Activism in the Twentieth Century*. Minneapolis, MN.

February 2008: American Society for Environmental History. "When the City Gets Too Close: Saving Hull's Gulch and Building Community in Boise, Idaho, 1980-2000," as part of the panel: *When Wild Isn't Wild Anymore: Negotiating the Boundaries Between Humans and the Wild*. (Also served as member of the Local Arrangements Committee for this conference.) Boise, ID.

October 2007: Western History Association. "Los Angeles: Sprawling Metropolis or Urban Park Haven? The Struggle for a City's Identity in the Santa Monica Mountains: 1960-1978," as part of the panel: *The Boundaries of Nature: Cities, Counties, and Tensions around Parks in the West*. Oklahoma City, OK.

March 2000: American Society for Environmental History. "Deschutes and After: The State's Rights Issue in River Management, 1947-1956," as part of the panel: *Whose Rivers Are They?: The Politics of River Management in the Pacific Northwest*. Seattle, WA.

Teaching/Academic Experience and Other Talks

In addition to teaching in the History, Urban Studies, and Environmental Studies Departments at Boise State University, Dr. Stevens also serves on graduate student committees, supervises graduate and undergraduate interns each semester, and advises graduate students on original research.

Boise State University, Boise, ID

Spring 2019: Urban Field School. A History of Brownfields and their Rehabilitation in Urban Centers.

Fall 2018: Urban Studies/History: U.S. Urban History, 1877-present.

Summer Session 2017: Investigate Boise Series: "Green Cities." Co-taught with Professor Amanda Ashley, Boise State University, Boise, Idaho.

Spring 2014/2015: Department of Environmental Studies. United States Urban Environmental History.

Fall 2013: Department of History. Upper-division Environmental History.

Spring 2010: Department of History. Upper-division Environmental History.

Spring 2010: Department of History. 3-day workshop entitled, "Women and the Urban West."

2006: Teacher/Leader. Department of History. 3-day workshop entitled "History of the Boise Foothills."

Interns Mentored and Graduate Student Committees

2019: Kathy Hansen, M.A. Boise State University (History)
2019: Jenna Shaw, B.A. Boise State University (Urban Studies)
2018: Jennifer Tucker, M.A., Boise State University (History)
2018: Maicee Byrd, B.A., Boise State University

2017: Erin Lozowski, B.A., Boise State University
2017: Cyrus Forman: Ph.D. Candidate, History, University of Washington
2017: Sam Jones, B.A., Boise State University
2016: Adam Behrman, Ph.D. Candidate, History, University of Wisconsin-Madison
2016: Molly Myers, B.A., College of William & Mary
2015: Sadi Mosko, B.A., Columbia University
2014: HannaLore Hein, M.A., Boise State University (History)

University of California

1999: Teaching Assistant. Department of History, Davis.

- United States Environmental History.
- United States History, 1860-present.
- Modern European History

1994-1995: Teaching Assistant. Department of History, Santa Barbara.

- United States History, 1860-present.

Other Invited Talks

May 2018: "This Ain't Going to be No Lunch Bucket Town: Boise's Evolving Urban Identity," an invited lecture at the Osher Institute for Lifelong Learning, Boise, Idaho.

January 2017: Invited speaker, Environmental and Natural Resources Law Section, Idaho State Bar: "Digging In: Historical Research in Your Natural Resources Case."

October 2014: Invited speaker, Idaho State Archives Opening Ceremony, Acquisition of the Snake River Basin Adjudication Collection.

August 2013: Featured Speaker, Idaho Environmental Forum's Boise River Conference: "History of Irrigation in Idaho."

April 2013: Featured Speaker, Boise 150 Celebration: "The History of Boise's Green Spaces."

October 2012: Online Panelist: "Careers for Consulting Historians," The Versatile Ph.D.

June 2015/July 2012/July 2011/July 2010: NBI, Inc. A class on historical research for attorneys earning Continuing Legal Education credit. Boise, Idaho.

June 2012: Speaker at the Idaho Water Users Association's Water Law Seminar on "Documenting Your Water History." Sun Valley, Idaho.

Grant Awards

2018-2019: National Endowment for the Humanities: Digital Projects for the Public. "'This Ain't No Lunch Bucket Town': The Evolution of Urban Identity in Boise, Idaho." ($30,000)

2018-2019: City of Boise Arts & History Grant. Oral histories "This Ain't No Lunch Bucket Town." ($4,000)

Professional and Academic Awards

2017: Mayor's Award for Excellence in History, Boise, Idaho. (Given to a single individual biennially.)

2017: Recipient of the Excellence in Consulting award, *National Council on Public History*, for *100 Years of Idaho Power History* Traveling Museum Exhibit.

2013: Honorable Mention for the Excellence in Consulting award, *National Council on Public History* for *Voices of Courage, Champions of Excellence*, a history of the Idaho Education Association.

2012: Woman of the Year Award, *Idaho Business Review*

2011: Accomplished Under 40 Award, *Idaho Business Review*

2007: Consortium for Women and Research, Research Grant, University of California

2008: Consortium for Women and Research, Travel Grant, University of California

1999: Department of History Research Block Grant Award, University of California, Davis.

Other Professional Experience and Service to the Profession

2017-2018: Program Evaluator. Invited community member for evaluation of Boise State University's Master's in Applied Historical Research.

February 2018: Invited commenter: Treasure Valley Water Atlas, a project supported by the National Science Foundation.

2017: Graduate student mentor and sponsor, University of Washington, for students desiring applied training outside of the academy.

2016-present and 2008-2013: Mayor-appointed member, Boise City Planning and Zoning Commission. Commission Chair, 2012-2013.

2014-2016: Board Member, Idaho Environmental Forum.

2012-present: Member and chair, Consultant's Committee, National Council on Public History.

2012-present: Contributor, *Consultant's Corner*, National Council on Public History.

2011-present: Governor-appointed member, Idaho State Historical Records Advisory Board.

2012-2014: Member, Education Committee, *Preservation Idaho*.

2007- 2008: Member, vice-president of the Board of Trustees, Land Trust of the Treasure Valley.

2005-2008: Chair, Boise City Historic Preservation Commission.

2003-2008: Member, Boise City Historic Preservation Commission.

2004: Graduate, Leadership Boise Program, Boise Chamber of Commerce

2002-2003: Historic Preservation Chair, Newsletter Editor, and Board Member, North End Neighborhood Association. Worked with local historians and architects to preserve and maintain the historic resources of Boise's North End neighborhood.

2001-2002: Market Intelligence Manager, PeopleSoft, Inc., Pleasanton, CA. Collaborated with executives, including CEO, to determine competitive positioning for sales and marketing in the dynamic e-business software sector. Planned international expansion of market intelligence team. Interacted regularly with industry analysts.

1999-2001: Manager, Competitive Intelligence, Siebel Systems, Inc., San Mateo, CA. Worked closely with executive team, including COO, to devise corporate strategies to remain ahead of the competition in the software industry. Traveled internationally to present strategies to sales teams and executives.

1995: Water Policy Researcher/Analyst. Environmental Policy Center, San Francisco, CA. Researched local government policies regarding water efficiency and water quality. Updated information on the Center's Web site, followed trends in policy making and assisted local government clients in implementing policies.

Conferences Attended

American Society for Environmental History: 2017, Chicago; 2016, Seattle; 2014, San Francisco; 2008, Boise; 2006, St. Paul; 2000, Seattle; 1999, Tucson; 1995, Las Vegas.

National Council on Public History: 2019, Hartford; 2018, Las Vegas; 2016, Baltimore; 2010, Portland**.**

American Historical Association: January 2013, New Orleans.

Western Association of Women Historians: May 2009, Santa Clara.

Berkshire Conference on the History of Women: June 2008, Minneapolis.

Society for American City and Regional Planning: October 2017, Cleveland; October 2009, Oakland.

Western History Association: 2016, St. Paul; 2012, Denver; 2009, Denver; 2008, Salt Lake City; 2007, Oklahoma City.

FORUM, National Association for Preservation Commissions: July 2006, Baltimore.

California Committee for the Promotion of History: October 1995, Sacramento.
